A total of 319 radical mastectomies have been performed at the Pondville Hospital, with 12 postoperative deaths, a mortality rate of 3.8 per cent. Careful scrutiny of these cases brings to light several factors of importance (Table 2). Three patients (Cases 10, 11 and 12) succumbed to sepsis within a single month during a period when there were a considerable number of cases of streptococcal sore throat in the hospital. These patients,

AGE INCIDENCE

The average age was 50.3 years in the early death group, 51.2 years in the late-death group and 51.1 years in the cured group. Sixty-five per cent of the patients in the early-death group had passed the menopause, 60 per cent in the late-death group and 57 per cent in the cured group. Naturally no significance can be attached to these figures. The data on the menstrual status are further complicated by the practice of carrying out prophylactic artificial menopause in a number of the young patients after radical mastectomy. One of us (G. W. T. §) suggested elsewhere that this procedure is of doubtful value. It is interesting to note, however, that the present study lends no support to the belief that mammary carcinoma is more malignant in younger than in older women.

Analysis of the groups in regard to fertility status and lactation was inconclusive, although there appeared to be a slight tendency for the cured patients to be less fertile than those in the other two groups.

§Taylor, G. W. Evaluation of ovarian sterilization for breast cancer. *Surg., Gynec. & Obst.* 68:452-456, 1939.

DURATION OF DISEASE

It was natural to expect that the preoperative duration of disease in the patients cured for five years or more would be shorter than that in those who did badly following operation, the figures bear out this assumption. The average preoperative dura-

SKIN INVOLVEMENT

Although the classic description of carcinoma of the breast includes skin retraction and puckering, it is commonly recognized that this condition represents a later stage of the disease. Analysis of our cases in regard to the frequency and char-

| 11 | 9105 | 59 | 150 | 180/84 | Nitrous oxide, oxygen and ether | 37 days | Sepsis |
| 12 | 2170 | 45 | 153 | 140/76 | Nitrous oxide, oxygen and ether | 9 days | Sepsis |

tion in the cured cases was 7.7 months, as contrasted with 12.0 months for the patients who subsequently died. Sixty-three per cent of the cured patients were first seen within six months of onset, and 84 per cent were seen within one year. The corresponding figures for the fatal cases were 54 and 71 per cent.

SIZE AND LOCATION OF LOCAL LESION

The lesions were classified in three groups, small, up to 2 cm in diameter, medium, 2 to 4 cm, and large, over 4 cm (Table 3). It may be seen that

TABLE 3. *Size of Lesion in Relation to Outcome*

| SIZE OF LESION | EARLY-DEATH GROUP | LATE-DEATH GROUP | CURED GROUP |
|----------------|-------------------|------------------|-------------|
| | % | % | % |
| Small | 0 | 14 | 44 |
| Medium | 21 | 33 | 42 |
| Large | 79 | 53 | 14 |

the early-death group showed a great preponderance of large sized lesions. It is equally impressive that 86 per cent of the cured cases presented lesions less than 4 cm. in diameter. These figures show very strikingly the relation between the size of the lesion and its curability.

Careful analysis was made of the location of the lesion in the breast in relation to its curability. No findings of any significance resulted from this study, possibly because the groups were small. Growths in the upper outer quadrant predominated in all three groups of cases, perhaps excessively in the groups with subsequent fatal outcome.

acter of skin involvement is shown in Table 4. In the early-death group in no case was the skin not involved, while in nearly half the cases (43 per

TABLE 4. *Skin Involvement in Relation to Outcome*

| TYPE OF INVOLVEMENT | EARLY DEATH GROUP | LATE DEATH GROUP | CURED GROUP |
|---------------------------------|-------------------|------------------|-------------|
| | % | % | % |
| No involvement | 0 | 20 | 61 |
| Dimpling alone | 0 | 61 | 32 |
| Dimpling plus edema | 7 | 5 | 5 |
| Dimpling plus edema and redness | 11 | 5 | 0 |
| Ulceration | 14 | 10 | 2 |
| Paget's disease | 11 | 0 | 0 |

cent) the involvement was more extensive than dimpling alone. Among the patients dying of recurrence after eighteen months, 20 per cent presented no evidence of skin involvement, and only 20 per cent showed more involvement than simple dimpling. In the cured group there was no evidence of skin involvement in about a third of the cases, and only 3 patients (7 per cent) presented involvement more grave than dimpling.

It is evident that dimpling in itself does not increase the gravity of the prognosis. However, when edema, redness or ulceration is superadded, the likelihood of cure is markedly diminished.

INFLAMMATORY CARCINOMA

There were 8 cases of so-called "inflammatory carcinoma." Five of these were in the early-death group and 3 in the late-death group. Five patients had received intensive preoperative radiation, of whom 4 died early and 1 died late. In the cured group there were no cases of inflammatory carcinoma and no patients had had intensive preoperative radiation. Attention may be drawn to those

cases in which preoperative radiation was employed. These were all considered locally inoperable by the usual criteria when first seen. Subsequently, with good regression of the tumor and negative x-ray studies as regards distant metastases, they were considered to be operable. The consistently bad outcome convinces us that an inoperable lesion cannot be made operable by radiation, despite marked regression.

SECONDARY RADICAL MASTECTOMY

Eight patients were submitted to radical mastectomy after previous inadequate surgery performed elsewhere. Five of these presented frank recurrence at the time of their secondary operation, 1 died early, the other 4 late. The 3 patients who were cured by secondary radical operation showed no evidence of residual disease in the specimen removed at operation. These findings suggest that a secondary radical operation for frank recurrence is not likely to be successful.

AXILLARY INVOLVEMENT

The influence of axillary involvement on the prognosis in carcinoma of the breast has been repeatedly observed and emphasized in end-result studies in large series of cases. Our present study confirms the findings of others. Axillary nodes were involved pathologically in 90 per cent of the patients who died within eighteen months, in 72 per cent of those who succumbed to later recurrence and in only 32 per cent of those who were cured. We were again interested in the question of the accuracy of clinical appraisal of axillary-node involvement. In a total of 265 axillary examinations, the clinical appraisal was confirmed by the pathologist in 191 cases, and failed

to be confirmed in 74 cases (28 per cent), as shown in Table 5. Errors of appraisal were fairly equally distributed between the two possibilities of considering an innocent axilla as involved and of failure to detect the presence of metastatic in-

TABLE 5 *Comparison of Clinical Axillary Examinations with Pathological Examinations*

| STATUS | No. of Cases |
|--|--------------|
| Positive clinically and pathologically | 94 |
| Negative clinically and pathologically | 97 |
| Negative clinically, positive pathologically | 44 |
| Positive clinically, negative pathologically | 30 |
| Total | 265 |

volvement. These figures again emphasize the danger of giving too much weight to the clinical estimate of axillary involvement in planning appropriate treatment.

CONCLUSIONS

On the basis of this study, the prognostic importance of the clinical characteristics of carcinoma of the breast, as it is presented for treatment, is apparent. Large lesions and those with skin involvement or extensive axillary involvement offer a poor prognosis, in many cases so poor as to contraindicate surgical intervention even in the absence of remote metastasis. The operative risk must be given careful consideration. Old age, obesity and hypertension seem to increase the hazard. While it is still impossible to prognosticate accurately in any single borderline case we believe that the chance of cure should be carefully weighed against the operative risk and the normal life expectancy. Palliative measures may well be indicated more often than they are now employed.

THE ANTEMORTEM RECOGNITION OF PULMONARY EMBOLISM*

ALLEN S. JOHNSON, M.D.†

SPRINGFIELD, MASSACHUSETTS

TO THE fourth year medical student the clinical diagnosis of fatal pulmonary embolism apparently presents few difficulties. A rather obese middle-aged woman's recovery from an abdominal operation has been uneventful except for a mild phlebitis. During the second week she calls for the bedpan and then, clutching her chest, utters a gasping cry and expires. That the reliability of this composite picture may be open to question is hardly suggested by McCrae's¹ description: "In the case of a large embolus blocking a main branch of the pulmonary artery death may be almost instantaneous, perhaps after a cry. In other cases there are sudden severe dyspnea, thoracic pain, distress and cyanosis, followed by unconsciousness and death." Emerson² elaborates on this by saying that the patient with rapidly fatal pulmonary embolism first experiences sudden pain or tightness in the chest: "He becomes ashen in color anxious, then cyanotic and dyspneic. Pulmonary edema develops, the pulse becomes feeble and death follows in a few minutes or hours." Homans³ stresses sharp, stabbing, pleuritic pain, with orthopnea and blood-tinged sputum. Barnes⁴ points out, as does White,⁵ that pulmonary embolism and coronary thrombosis have many clinical features in common, such as sudden onset, pallor and sweating, precordial pain, weakness, vomiting and collapse, with fall of blood pressure and rise in temperature, pulse, respirations and leukocyte count. White says: "The majority of case reports of pulmonary embolism describe the patient as being in a state of shock with feeble pulse, apprehension, sweating, pallor, dyspnea and low blood pressure. Cyanosis is frequently present and often extremely marked whereas in other patients pallor predominates. Whether or not chest pain is present depends largely on the analysis of the examiner." Unilateral rales and signs of consolidation, he adds, may be demonstrated if the patient lives long enough. The x-ray picture is seldom helpful for the first twenty-four hours, and may not be diagnostic even then. Both Barnes and White believe that the electrocardiogram furnishes valuable diagnostic evidence. Hosoi⁶ stresses the importance of these clinical features, and lists them in the following

order of frequency, after a study of 64 cases confirmed by autopsy: dyspnea, restlessness, cyanosis, sweating, vomiting, pain in the chest and cough, with or without bloody sputum. He does not give the frequency distribution of these symptoms, however, nor does he state how many of them we may expect to find in one and the same patient.

This unanimity of opinion as to the diagnostic criteria for pulmonary embolism should render an accurate diagnosis a simple matter, even for the tyro. And if all the criteria are present, it is. But a study of 43 fatal cases in which autopsy showed pulmonary embolism to have been the immediate cause of death reveals that only 3 cases answered the composite description quoted by White. In 9 cases the clinical picture ante mortem was so atypical as to make the diagnosis of pulmonary embolism unwarranted, even in retrospect. Furthermore, during this study I encountered a significant number of patients who presented a sufficient number of these criteria ante mortem to warrant a diagnosis of pulmonary embolism but in whom the pathologist found sepsis, without evidence of embolism, as the cause of death. Because of other lethal states which resembled pulmonary embolism clinically, and the cases of actual embolism which masqueraded as shock, coronary thrombosis or bronchopneumonia, this study was undertaken in order to reappraise the validity of accepted diagnostic criteria.

Since the material for the study came from three different institutions with widely varying autopsy rates, a statistical analysis of the incidence of pulmonary embolism is futile. Hosoi⁶ cites 1 such death per 1000 hospital population. Pilcher⁷ gives the same incidence for surgical cases. Henderson⁸ found that fatal cases of pulmonary embolism represented 6 per cent of all postoperative deaths during the period studied. It is evident, therefore, that this entity is of more than academic importance.

In Henderson's series the average age was about fifty-three years, which was ten years older than the average of 1000 consecutive adult surgical patients used as controls. The average age in the present study was sixty years, owing to the preponderance of cancer patients who fall into the higher age brackets. The patients were almost equally divided between the two sexes, there being 22 men and 21 women. Data on their state of nutrition was not obtainable. Henderson's patients

*From the Cancer Section, Westfield State Sanatorium and the Pondville Hospital (Worcester), Massachusetts Department of Public Health, and the Springfield Hospital.

†Visiting physician, Westfield State Sanatorium; assistant visiting physician, Springfield Hospital.

were 13 pounds overweight, and the importance of obesity has also been stressed by Snell,⁹ although its exact significance is not clear from his report. Only 26 of the patients in my series developed fatal pulmonary embolism after an operation, but all 43 were suffering from some sort of surgical lesion. The type of anesthetic was probably not significant, in view of the relative frequency of the various types of anesthetic used in all surgical cases. Fourteen patients had a general anesthetic, 6 local anesthetic, 3 spinal anesthetic and 2 a combination of two or more anesthetic agents. The seriousness of postoperative infection in predisposing the patient to pulmonary embolism has been stressed by many investigators. Henderson found it in 44 per cent of his fatal cases. Robertson¹⁰ in an analysis of 146 fatal cases found phlebitis in only 4 per cent. In my study, 17 of 43 fatal cases had shown some sort of complication, usually sepsis or phlebitis, prior to the development of pulmonary embolism. Of the 26 patients who had undergone operation, 13 had had some sort of postoperative complication. That is, of the 17 cases with complications, 13 occurred in the operated group and only 4 in the unoperated. Four of the 26 operated patients had a postoperative phlebitis which was recognized ante mortem. But only 1 of the 17 unoperated patients had a demonstrable phlebitis, and this case was subjected to surgery, if a blood transfusion can be so classified.

The interval between operation and death varied from a few minutes to thirty-six days, with an average of ten days. Ten of the 26 operative deaths occurred during the first postoperative week, 8 during the second and 5 during the third. Thus far the results of this study appear to reflect the commonly accepted views which form the basis of my hypothetical medical student's easy assurance. The catastrophic suddenness of fatal pulmonary embolism is more apparent than real. Robertson found that in 39 per cent of 146 fatal cases the patients gasped, fainted, became pallid and died within one hour, whereas in 61 per cent they developed chest pain, cyanosis and hemoptysis, and lived several hours or days. Hosoi⁶ states that in 20 per cent of 64 fatal cases the patients died suddenly, while in 60 per cent they lived one to three days after operation. Unfortunately, the actual interval between the onset of symptoms and death is not made clear. In my series 13 patients died within one hour of the onset of symptoms. The remaining 30 lived from several hours to several days.

Dyspnea — labored as contrasted with merely rapid respiration — was the commonest finding,

but it occurred in only 28 of the 43 cases. In 1 aged patient it was the only clue and suggested congestive heart failure rather than embolism. Twenty-seven patients had an elevated pulse, and 23 elevated respirations. Cyanosis was present in 22 cases and was the only sign or symptom in 2. Marked weakness or actual collapse was observed in 17 cases, and in 6 it was the only evidence on which a diagnosis could have been made. Almost as frequent was sweating, which occurred in 16 cases. Fever was present in 16 cases, but 10 of these patients had pre-existing sepsis, which was probably responsible. Thirteen complained of chest pain, only 1 described this as a smothering sensation, whereas the rest referred to it as definite pain. Seven vomited, usually dark-brown material, with the onset of symptoms. This episode was clearly distinct from any postanesthetic or other postoperative complication, and occurred in patients who had been entirely free of gastric symptoms. Restlessness was frequently noted, but it was less common than in Hosoi's⁶ series. A fall of blood pressure was noted in only 5 patients, but in 1 case it actually rose to 240 mm, systolic. Unfortunately, the catastrophic nature of most of these mishaps precluded blood pressure determinations or adequate examination of the chest, so that these figures are not significant. Cough and sputum were infrequent and were not always associated in the same case. Pallor was observed in only 2 cases, in contrast to cyanosis, which occurred in 22. X-ray photographs were taken in only a few cases and failed to reveal pulmonary lesions. No electrocardiograms were taken. One Cassandra-like observation was recorded in many of the progress notes and may be significant before any definite symptoms developed: the patient frequently complained of not "feeling just right," or it was observed that he was "not doing well," or had failed to rally from the operation, patient and physician alike seemed to realize that all was not well, but the vague and amorphous character of the complaints concealed their significance. In this study, whereas 28 patients showed dyspnea, 27 tachycardia, 23 elevated respiration, 22 cyanosis and 17 marked weakness or collapse, only 11 of the 43 patients manifested all five of these criteria, and only 1 had them all plus sweating, fever, chest pain and vomiting. In 9 cases the picture was so bizarre or ambiguous that a clinical diagnosis of fatal pulmonary embolism seemed unwarranted, even in retrospect after the autopsy. The following condensed case histories are illustrative.

CASE REPORTS

CASE 1. C. McC. (3111P), a 76-year-old man with carcinoma of the face, had received both x-ray and radium

treatment. He grew steadily weaker and lapsed into coma and died within an hour without significant change in temperature, pulse or respirations. At autopsy several large branches of the pulmonary artery were found to be occluded by a recent clot.

CASE 2. C. T. (267P) a 26-year-old man with carcinoma of the parotid had had radium seeds implanted in the growth. A few days before death he developed erysipelas and began to go steadily downhill in spite of serum. He died apparently of sepsis without any striking abnormality of temperature, pulse or respirations. Autopsy revealed a clot in the left pulmonary artery.

CASE 3. A. B. (14951P) a 70-year-old woman with carcinoma of the cecum, had a colectomy under local anesthesia. She failed to rally from the operation, became stuporous and seemed to go into shock in spite of transfusion immediately after operation. Eighteen hours after operation the blood pressure had risen to 260/58 compared with a preoperative level of 160/70 but she continued to go downhill and did not regain consciousness. Just before death which occurred 24 hours after operation there was slight cyanosis and coughing. The temperature, pulse and respirations were slightly elevated just before death but not during the preceding period of unconsciousness. Autopsy revealed bilateral thrombosis of the pulmonary artery.

CASE 4. M. E. (9973P), a 73-year-old man with inoperable carcinoma of the stomach, was apparently making an uneventful recovery from exploratory laparotomy. On the 4th postoperative day he collapsed without premonitory signs or symptoms and died within a few minutes. At autopsy emboli were found in both pulmonary arteries.

CASE 5. S. H. (5705P), a 79-year-old man, had received x-ray and radium treatment for carcinoma of the tonsils. He became markedly cachectic and dehydrated and died apparently from cachexia without change in temperature, pulse or respirations. Pulmonary embolism of the right lower lobe was found at autopsy.

CASE 6. J. C. (8654P) a 55-year-old man, had carcinoma of the rectum. Four days after posterior excision second stage, the posterior pack was removed because of sepsis. He continued to go downhill with signs of extensive sepsis and renal insufficiency. He died on the 26th postoperative day apparently of sepsis and renal insufficiency having shown marked elevation of temperature, pulse and respirations for the previous 6 days. Autopsy revealed a thrombus in the left pulmonary artery and multiple emboli in the branches leading to the right lung.

CASE 7. G. D. (7750P) a 70-year-old man, had inoperable carcinoma of the stomach. On admission for terminal care, cyanosis of the right hand was observed. On the day before death there was definite gangrene of the hand. The patient became stuporous and died quietly 2 days later with no significant signs or symptoms except a slight rise in the temperature, pulse and respirations just before death. Autopsy revealed emboli in each pulmonary artery and in the right axillary artery.

CASE 8. G. T. (7419P) a 54-year-old man had a right nephrectomy under spinal anesthesia for a hypernephroma. Three days later he became distended and the pulse rose to 130 although the temperature remained normal and the respirations did not rise until just before death. While a duodenal tube was being passed to relieve the distention the patient stopped breathing and died. Autopsy revealed

a thrombus in the branch of the pulmonary artery leading to the right upper lobe.

CASE 9. M. B. (10734P) an 81-year-old woman had been receiving palliative x-ray treatment for inoperable carcinoma of the breast. Six days after the last treatment she lapsed into coma without any premonitory signs or symptoms and died quietly a few hours later. The only positive physical findings were elevations of the pulse and respirations and incontinence, just before death. A thrombus in the branch of the pulmonary artery leading to the right lower lobe was found at autopsy.

If such clinical ambiguity exists in cases proved by autopsy one can only speculate on the validity of the 22 deaths from pulmonary embolism reported¹¹ in Massachusetts in 1935, in view of the fact that only 4 were proved by autopsy.

In Hosoi's study, 42 per cent of the postoperative emboli were found at autopsy to be in the lower lobes, more often on the right side (in the ratio of 2:1). Forty-two per cent were in the main pulmonary artery or in one or both of its branches. In my group both main branches were the ones predominately involved, but the group is too small to warrant statistical analysis.

Embolectomy has not proved a conspicuous success and the value of papaverine administered intravenously has not yet been established. Further more, before any lifesaving form of therapy can be instituted the clinical diagnosis of pulmonary embolism must be made. It is evident that in about two thirds of the fatal cases the patients survive long enough for the application of some remedial measure, provided one can be found. But an appreciation of the clinical features of pulmonary embolism is essential if one's suspicions are to be aroused to the point of securing whatever laboratory studies may eventually prove definitely diagnostic and warrant heroic measures.

CONCLUSIONS

This study emphasizes the frequency and seriousness of pulmonary embolism, and suggests that its possibility should be considered in any patient who is not doing well even though he has undergone no operation and presents no signs of infection. Dyspnea, tachycardia and cyanosis are early and frequent signs. Although often accompanied by collapse, this feature may be absent or may occur alone. Finally, there appears to be no single criterion short of autopsy by which the diagnosis of pulmonary embolism can be infallibly established or excluded. It is believed, however, that if it is remembered that this condition can mimic, and be mimicked by, coronary thrombosis, bronchopneumonia, sepsis and surgical shock, greater diagnostic acumen will be developed.

REPORT ON MEDICAL PROGRESS

OTOLARYNGOLÔGY

CARLYLE G FLAKE, M D *

BOSTON

RECENT advances in otolaryngology can best be considered under the following headings ears, nose and sinuses, nasopharynx and pharynx, and larynx, trachea and bronchi

EARS

Otitis Media in Scarlet Fever

According to Wesselhoef¹ suppurative otitis media is the most important complication of scarlet fever. This conclusion is the result of his own experience with 10,000 cases of scarlet fever and a survey of the literature on this disease. The incidence of purulent otitis media in 370,000 cases of scarlet fever gleaned from the literature was 12 per cent, all the reports from various parts of the world giving approximately the same figure. This would seem to indicate that climate, which plays an important role in the morbidity of scarlet fever, exerts no influence on the incidence percentage of ear infection. The incidence of scarlet fever in the first year of life is low, but when it does occur, otitis media is frequent, although not so frequent as in the second and third years of life when almost half the patients developed otitis media. The importance of otitis media is due to its frequency and to the complications which arise from it, such as permanent deafness, mastoiditis, sinus thrombosis, septicemia, petrositis and meningitis. While infection of the middle ear may happen at any time during the course of scarlet fever, most cases occur after the first week, and particularly between the fourteenth and twenty-first days, the same period in which there is a peak for the other suppurative as well as nonsuppurative complications, such as nephritis, arthritis, endocarditis and purpura hemorrhagica. When German measles or chicken pox occurs in combination with scarlet fe-

ver the incidence of otitis media does not rise, but with measles or the common cold there is a marked increase in otitis, and with diphtheria the incidence of otitis is highest of all. While in uncomplicated diphtheria the incidence of otitis media is only 3 per cent, diphtheria that occurs during convalescence from scarlet fever raises the incidence to about 65 per cent. This is pointed out as a striking example of the enhancement in virulence of hemolytic streptococci through symbiosis. As to the effect of the removal of the tonsils and adenoids on the complicating ear infection, Wesselhoef concluded that the operation exerts no beneficial influence on the incidence of middle-ear abscess or mastoiditis. The value of tonsillectomy during the convalescence from scarlet fever was regarded as an entirely different matter. The practice of removing large and infected tonsils and adenoids after the third week is now well established as a safe procedure that often has a good influence on the course of suppurating ears and other complications. Paracentesis of the eardrum is of value to relieve pain or to provide adequate opening. But the influence of paracentesis on the course of otitis media is not so great as most textbooks indicate. In regard to the value of cod-liver oil as a preventive of middle-ear complications, Wesselhoef points to a study² done on the scarlet-fever wards of the Boston City Hospital, where large doses of cod-liver-oil concentrate were administered to 500 patients with no benefit.

Otitis Media Due to Type 3 Pneumococcus

As the infecting agent in otitis media, the Type 3 pneumococcus is one of the most treacherous organisms with which the otologist has to deal. It often acts in an insidious manner, giving rise to few symptoms while causing great destruction of bone. Ears infected by this organism are much

*Assistant in surgery Harvard Medical School visiting otolaryngologist Children's Hospital Boston.

more likely to be the origin of intracranial complications than are those infected by the hemolytic streptococcus. While the use of sulfanilamide and sulfapyridine has undoubtedly reduced the number of complications from middle-ear disease due to this organism, and has unquestionably cured a great many, these drugs should still be regarded as an adjunct to the treatment. The patient should be watched even more carefully than before, for the drugs frequently produce a masking effect on the course of the infection that may be confusing or misleading. An analytic study was made by Maybaum and Druss¹ of 73 patients who had middle-ear and mastoid infection due to the Type 3 pneumococcus. The disease in most of the cases ran the usual clinical course of infection of the middle ear, followed by mastoiditis or intracranial complication. Mastoidectomy was performed on 69 patients. In 46 cases there was marked impairment of hearing. These authors emphasize the point, already known, that pronounced impairment of the hearing in the presence of an apparently normal tympanic membrane, or one only slightly thickened, suggests a Type 3 pneumococcus infection. There was bemicranial pain in 44 cases. Tenderness over the mastoid was noted in 49 cases and was not present in the others, even when a subperiosteal abscess developed later. The x-ray findings in the mastoid processes were not characteristic. The average duration of symptoms before operation was thirty-three days, a longer interval than is ordinarily observed in streptococcal infections of the mastoid. In 41 cases there was extensive destruction of bone in the mastoid, and frequently marked softening without actual pus formation. In 23 cases a perineural abscess was noted, and in 9 an epidural abscess of the middle or posterior fossa was seen. Of the 73 patients studied, 59 were discharged as improved and 14 died, a mortality rate of 15 per cent. Prolonged observation of the patient after complete healing of the mastoid is regarded by these authors as of extreme importance.

Aero-otitis Media

With the development of travel by air a condition known as aero-otitis media is becoming more prevalent. This has been defined as an acute or chronic traumatic inflammation of the middle ear, caused by a pressure difference between the air in the tympanic cavity and that of the surrounding atmosphere. It commonly occurs during marked changes in altitude, and is characterized by inflammation pain tinnitus and deafness. According to Lovelace, Mayo and Boothby,⁴ failure to ventilate the middle ear voluntarily may be the result of inexperience, carelessness or failure to

awaken sleeping passengers on transport planes. The most frequent causes of inability to ventilate the middle ear are stenosis of the Eustachian tube as a result of an acute or chronic infection of the upper part of the nose and nasopharynx, paralysis of the soft palate or superior pharyngeal muscles, enlargement of the pharyngeal or tubal tonsil, in inflammatory conditions of the Eustachian tube or middle ear and scar tissue about the ostium of the Eustachian tube. In acute aero-otitis media there is first a feeling of fullness in the middle ear due to a negative or positive pressure equivalent to 3 to 5 mm of mercury. As the decrease in pressure becomes more marked the hearing becomes less acute. There are tinnitus, increasing pain and, sometimes, vertigo. Higher pressures produce agonizing pain. The tympanic membrane ruptures when it is under an air pressure equivalent to 100 to 150 mm of mercury. The symptoms are relieved by the opening of the Eustachian tube, if the negative pressure has not become so great as to render this impossible. In chronic aero-otitis media there is partial deafness, which may be more pronounced on one side and vary from day to day, with a sensation of fullness and stiffness in the ears and with head noises. This deafness is made worse by changes in altitude and by acute infections of the upper respiratory tract. On examination the eardrums are either bulging or, more frequently, retracted. The drum membrane is dull and lusterless, and sometimes slightly thickened. The light reflex is diminished or absent. The hearing is decreased, and the deafness is of the conductive type. One of the authors, who was himself subject to this type of auditory distress, sometimes for two or three days, after traveling in an airplane, administered by inhalation a mixture of 80 per cent helium and 20 per cent oxygen to several subjects, in the hope of alleviating or preventing the condition. As a result of these experiments the authors suggest inhalation of helium and oxygen as an adjunct in the prevention and treatment of acute aero-otitis media. Further measures for the alleviation of this condition, as advocated by Armstrong and Heim,⁵ consist in swallowing, yawning, singing, autoinflation of the Eustachian tube and contraction of the salpingopharyngeal muscles. The use of vasoconstrictor drugs in spray form is suggested for those with an upper respiratory infection. Acute aero-otitis can also be relieved by instillation of water at about 110°F into the external auditory canal and the application of dry heat, together with the spraying of astringents into the nasopharynx every two to four hours. Inflation of the tympanic cavity may be done where necessary.

NOSE AND SINUSES

Allergy

It is the opinion of Hansel⁶ that too much surgery of the nose, sinuses and throat is being done without considering the factor of allergy. While surgical procedures are indicated in certain cases, results will not be satisfactory unless the allergic factors are controlled. There are often other associated evidences of allergy, such as asthma, bronchitis, bronchiectasis, gastrointestinal allergy, allergic headache, urticaria, eczema and angio neurotic edema, which must also receive proper attention from the allergic standpoint. In order that the patient may get the best possible care there must be close co-operation between the otolaryngologist and the allergist. Among the possible manifestations of allergy are aphthous stomatitis and canker sores, both of which are of relatively common occurrence. Some cases of gingivitis have been claimed by dentists to be of allergic origin. Tonsillectomy rarely has a distinct beneficial effect on respiratory allergy but may reduce the incidence of complicating infections. Among 200 children considered by Hansel for removal of the tonsils and adenoids, 26 had definite respiratory allergy. If the tonsils and adenoids are large in allergic children and obstruct the air passages they should be removed, because nasal respiration is thereby impaired. The operation should not be performed during the hay-fever season.

From a review of the current literature, Hansel gives the following summary of the status of ionization in nasal allergy. Many leading rhinologists consider ionization of the nasal mucosa a safe measure in the treatment of hay fever and perennial nasal allergy. On the other hand, the observations of several prominent allergists indicate that ionization does not give results comparable to those obtained by allergic methods of treatment. Several observers have shown that the use of escharotics in nasal allergy produces results equally as satisfactory as those obtained by ionization. So far no permanent destructive changes have been noted as a result of ionization. However, complications such as anosmia, neuralgia and sinusitis have been reported in a few cases. Satisfactory relief following ionization is apparently the result of a general desensitizing effect, as well as a shrinkage of the nasal tissues and the diminution of hypersecretion. Bronchiectasis as a complication of bronchial asthma is seen not infrequently, on the other hand, chronic bronchitis and bronchiectasis occur in the absence of definite asthma. Polypoid changes in the mucous membrane of the nose and paranasal sinuses similar

to those noted in cases of allergy commonly co-exist in bronchiectasis without asthma. According to Hansel few observers have paid any particular attention to the incidence of allergy in these patients, and the changes in the nose, sinuses and bronchi have been treated as though infectious in origin. Now the question arises as to the part played by allergy in bronchiectasis with or without co-existing sinus changes. Watson and Kibler⁷ observed that bronchiectasis is seldom found without some evidence of sinusitis. They also noted that many patients with bronchiectasis had some manifestations of allergy such as hay fever, asthma, urticaria, eczema and rhinitis. On studying the cytology of the nasal secretions they were impressed by the frequency of the high percentage of eosinophils. A similar study of the sputum likewise showed an abundance of eosinophils in a large percentage of cases. On this basis these authors began investigation and treatment of these cases from the allergic standpoint and were able to obtain most satisfactory results. Thus a new conception of the etiology of bronchiectasis that makes its prevention and recovery possible has been presented. The development of the disease is explained on the following sequence of events: a basal allergic bronchitis, atelectasis and eventually, after a variable length of time, bronchiectatic dilation.

Röntgen-Ray Therapy in Sinusitis

During the last ten years there has been an increased interest in roentgen-ray therapy of sinusitis. With few exceptions the articles on this subject have been contributed by radiologists. A review of the literature by Gatewood⁸ revealed an absence from the case reports of any uniform rhinologic study and a wide variety of roentgen-ray techniques, some authors favoring large infrequent doses and others preferring light doses scattered over a long period. It is generally agreed that x-ray therapy is most effective with certain types of hyperplastic sinus membrane. The best results are obtained in a subacute or recent sinusitis where there is marked infiltration, with little air space. Gatewood observed 22 cases before and after radiologic treatment. Four patients showed complete relief of symptoms, the clinical findings were entirely normal and the diagnostic films clear. These patients were considered, in a sense, well. Eight patients were symptomatically improved, but irrigations of the antrum of 3 showed purulent discharge. Ten patients thought that they were not helped symptomatically. Their x-ray films did not show any appreciable change from the originals, and clinical examination showed little or no difference from

the appearance before x ray treatment. Four of these 10 patients were operated on by means of the double Caldwell Luc operation. In each case the antrums were filled with hyperplastic mucous membrane and polypoid granulations. Cultures showed streptococci. The antral contents did not differ in appearance from those of others with this type of infection who had not been subjected to irradiation, with one exception, the same held true for microscopic examination. Gatewood believes that roentgen ray therapy for any form of sinusitis is in an early experimental stage, and that closer co-operation between the radiologist, the rhinologist and the microscopist must be obtained before the true effects of this type of therapy can be determined.

NASOPHARYNX AND PHARYNX

Thornwaldt's Bursa

Eagle⁸ reports 64 cases of nasopharyngeal bursa observed by him during the past six years. The persistent sac lies beneath the adenoids and empties by a short duct at the lower portion of this tissue. The sac extends upward and backward into the periosteum. It is apparently a persistent embryologic structure that lies dormant until traumatized or infected. In the majority of the cases symptoms due to the presence of the bursa were noted after the adenoids had been removed. Two forms of this disease are described: the cyst type (46 cases), in which the duct is occluded, and the crust type (18 cases), in which the duct is patent and the discharge is adequate but dries and forms crusts in the nasopharynx over the opening of the duct. The content of these cysts is invariably a jelly like clear or turbid substance. The symptoms in both types of the disease are practically the same: frequent upper-respiratory infections, postnasal discharge, a rather thick and tenacious material being most commonly described, headache, which is usually low occipital in type and daily or rather frequent in occurrence, and, in several cases, slight fever, especially following any attempt at local treatment of the region. Some patients with crust formation complained of a dull ache located in the nasopharynx. Obstruction of the Eustachian tube and referred pain to the ear were commonly noted. The crust type of pharyngeal bursa did not always present evidence of disease on examination, especially if the crust had recently loosened and fallen into the pharynx. A careful search may have to be made in order to find the pin-point duct orifice. The crusts were invariably conical in shape and faceted into the conical depression at the duct orifice, which is located at the lower border of the adenoid area. Cultures were made

in all operative and practically all nonoperative cases. A hemolytic *Staphylococcus aureus* was found in 19 patients, and a beta hemolytic streptococcus in 6. Mixed infections were common. Clinical diagnosis was made in all cases by examination with the nasopharyngoscope. Treatment consisted of complete removal of the sac by a thorough curetting of the entire adenoid area. This procedure necessitates much more force than is ordinarily used during an adenoidectomy. The Barnhill adenoid curet was found to be the most useful instrument for this operation. Twenty-five patients who were thoroughly curetted recovered completely from local nasopharyngeal symptoms.

Bulbar Poliomyelitis and Tonsillectomy

It has been pointed out that the incidence of bulbar poliomyelitis in children who have been recently tonsillectomized is much higher than that in any other group. Sabin¹⁰ presents conclusive experimental evidence that while mere transitory contact of the virus with the normal or injured pharynx or tonsils will not produce poliomyelitis, it is possible to infect monkeys when the virus in quantities of from one hundred to one thousand minimal cerebral infective doses is injected into the region of the tonsil. This area is for some reason more sensitive than is the abdominal, cutaneous or subcutaneous tissue. That the pathway of the virus is along a local peripheral nerve after tonsillopharyngeal injection is indicated by the high incidence of the bulbar type of the disease among these monkeys and evidence that the virus did not invade the central nervous system along the olfactory pathway. If the virus in the human being behaved as it does in a monkey—and there is no evidence that such is the case—one would expect that for the development of post-tonsillectomy poliomyelitis the virus would have to be present in the secretions or in the tonsils during the operation, and that infection would be facilitated by injection or postoperative suturing. That poliomyelitis virus does occur in the secretion of the upper respiratory tract and in the tonsils of apparently healthy human beings is already known although it is not clear whether the virus is more prevalent during the summer and early autumn than at other times of the year. These findings suggest that the season of high incidence of poliomyelitis is not a favorable period for operation on the upper air passages.

LARYNX, TRACHEA AND BRONCHI

Injury to the Larynx from a Duodenal Tube

The soft-rubber duodenal tube has come to have wide use in surgery and medicine as a siphon

for the treatment of postoperative gastric and intestinal distention and as a means of feeding patients who are unable or unwilling to swallow. The tube is commonly passed through the inferior nasal meatus to the pharynx and esophagus, and thus to the lower gastrointestinal tract. At the upper end of the esophagus the cricopharyngeus muscle, which has a sphincter-like action, grasps the tube and holds it in contact with the posterior surface of the cricoid cartilage and the posterior surfaces of the arytenoid cartilages. Even with the tube in place the patient makes some involuntary swallowing movements, and these serve to bring in even closer contact the tube and the posterior cartilaginous portions of the larynx. Considering the widespread use of the duodenal tube, accidents and untoward happenings are relatively uncommon. However, a note of warning is sounded by Iglauer and Molt,¹¹ who report 10 cases of severe injury to the larynx observed by them during a period of two years. Each of these patients had an indwelling tube in place for at least six days. Symptoms of laryngeal obstruction were so severe in 8 cases that a tracheotomy was necessary. Two of the 10 patients died. One had the tube down for only six days when she gradually developed signs of laryngeal obstruction. Postmortem examination of the larynx showed an acute ulceration through the entire thickness of the esophageal wall, with extension of the inflammation along the soft tissue about the cricoid cartilage and with involvement of the left arytenoid cartilage. Necropsy on the other patient showed, in addition to a severe laryngitis, three shallow ulcerations on the anterior wall of the esophagus in the region of the cricoid cartilage. In most of the 10 patients, evidence of injury to the larynx was first noted after permanent removal of the tube. The early symptoms included pain, dysphagia, blood-streaked sputum, hoarseness and croupy cough, accompanied by more or less dyspnea. Gradual increase in the severity of these symptoms occurred over a period of days or weeks, during which dyspnea became the prominent symptom and was so extreme that tracheotomy was necessary. The extreme dyspnea was explained on the basis of subglottic edema. Five of the patients are still under treatment for laryngeal stenosis, and none of them have been able to dispense with the tracheal cannula. Iglauer and Molt suggest that, in the presence of an indwelling duodenal tube, any signs or symptoms indicating esophageal or laryngeal involvement demand an immediate examination of the larynx, and removal of the tube if the larynx or hypopharynx shows any sign of inflammation. They further urge that wherever feasible the tube should be removed and cleaned at frequent

intervals and reinserted through the opposite nostril. The use of a small tube is desirable whenever possible.

New Technic for the Repair of Laryngeal Paralysis

Bilateral paralysis of the abductor muscles of the vocal cords is most often the result of operative trauma in the neck, such as is sometimes seen in the complications after thyroidectomy, inflammatory processes in the neck or severe edema. This type of paralysis may also be the result of tabes or bulbar palsy. Occasionally, mediastinal growths may involve both recurrent laryngeal nerves. Various procedures have been devised and used for the relief of this condition. They may be classified under four headings: permanent tracheotomy, nerve suture, cordotomy or cordectomy and cord displacement. Since the object of any operation should be to restore the functions of phonation and respiration, none of these procedures have, in the opinion of King,¹² given satisfactory results. He noted that the suprahyoid muscles pulled the larynx up during swallowing, while the infrahyoid group, including the omohyoid muscle, pulled it down. He has devised an operation consisting essentially of transposition of the omohyoid muscle to the arytenoid cartilage in recent cases, plus laryngeal reconstruction in cases of old involvement with contracture. The operation is preceded by a preliminary tracheotomy, and four to six weeks are allowed for the patient to become accustomed to a tracheotomy tube and for infection to clear up. In brief the operation consists in mobilizing the anterior belly of the omohyoid muscle and attaching it by sutures to the posterior surface of the arytenoid cartilage. The esophagus is not entered. The arytenoid cartilage is mobilized by cutting the ligamentous capsule of its joint on three sides — mesial, outer and posterior, the last of which also divides the fibers of the cricoarytenoid muscle. Where the paralysis is of long standing, it is also advisable to divide the interarytenoid muscle and fascia and to sever the joint capsule.

Complications of Acute Obstructive Laryngitis and Tracheotomy

A review of the literature by Graebner¹³ shows that comparatively few cases of mediastinal emphysema incident to acute obstructive laryngitis have been reported. Pneumopericardium has never been described as a complication of this condition. On the Croup Service of the Willard Parker Hospital in New York City, 5 patients were observed who had one or the other of these complications. Two patients had pneumopericardium within twenty-four hours after tracheotomy was done, 2 had pneumomediastinum, and in one of these

cases it was noted that air was present in the tissues during operation, while in the other it developed two days later with the exacerbation of a previously mild bronchopneumonia. The remaining patient did not have a tracheotomy, and pneumomediastinum was found after cough and expectoration developed, with evidence of infection in the lower respiratory tract. All the patients had nonspecific croup. Pneumomediastinum may be the result of severe physical strain, attacks of coughing in pertussis, operative procedures on the neck, thorax and abdomen, and perforating wounds of these regions. The evidence presented in these cases indicates a direct relation of pneumomediastinum and pneumopericardium to obstruction of the upper or lower part of the respiratory tract rather than to tracheotomy. The route by which air enters the pericardial sac is not known. No specific measures were required in these patients other than relief of all obstruction to respiration.

Six cases of acute laryngeal obstruction are reported by Michels.¹⁴ Three of the patients died. Pneumothorax and mediastinal emphysema occurred in 5 cases following tracheotomy. Michels believes that these complications occur more often than the literature suggests. In relation to the mechanism responsible for pneumothorax there are several anatomical factors to be considered. Injury to the lung or the dome of the pleura may easily occur in children during tracheotomy because of the close relation of these structures to the trachea, this is especially likely to happen should the incision be too low or deviate from the midline. Incising the pretracheal fascia and lifting it away from the trachea may allow air to enter the mediastinum. Closing a recent tracheotomy wound by stitching may also cause mediastinal emphysema. The experimental production of pneumothorax and mediastinal emphysema by the intrapleural route, with direct rupture of the parenchyma and the pleura, according to Kirschner¹⁵ requires a pressure equivalent to 100 to 300 mm of water. The intrapleural route, with dissection of

minute globules of air from the interstitial tissues along the great vessels to the hilus, is probably a commoner one when intrapulmonic pressure is increased by cough or any severe and sudden strain. After tracheotomy or any endoscopic procedure the patient should be closely observed. Increasing respiratory embarrassment demands a careful survey of the chest, and fluoroscopy or the taking of roentgen-ray films if necessary. Pneumothorax may be recognized by greatly diminished excursion of the affected side, displacement of the heart to the opposite side and a diminution or absence of breath sounds. The percussion note is usually tympanic, but if the amount of air present is small and the bronchi are full of mucus, there may be dullness. Mediastinal emphysema may be recognized by crepitant sounds following each heart beat. Tympany may be present over the area normally occupied by cardiac dullness, and the apex beat is often lost to inspection and palpation. Early recognition of these conditions is important so that some form of drainage can be instituted.

Complications of Acute Obstructive Laryngitis and Tracheotomy

A review of the literature by Graebner¹³ shows that comparatively few cases of mediastinal emphysema incident to acute obstructive laryngitis have been reported. Pneumopericardium has never been described as a complication of this condition. On the Croup Service of the Willard Parker Hospital in New York City, 5 patients were observed who had one or the other of these complications. Two patients had pneumopericardium within twenty-four hours after tracheotomy was done, 2 had pneumomediastinum, and in one of these

abated only with dilaudid. For one month prior to admission he noted many purpuric lesions in the skin of his feet. These became excruciatingly painful and required morphine for relief. An asthmatic attack occurred two days before entry and was characterized by wheezy breathing, dyspnea, orthopnea, a "tight chest" and the production of thick glairy mucoid sputum flecked with blood. Palpitation of the heart, without chest pain, was noted. Since his discharge he had taken Lugol's solution up to 100 drops a day. One week before re-entry he developed a swollen nose, noted excessive lacrimation and developed an iodine skin rash. The Lugol's treatment was stopped and relief was immediate. But on resumption of the therapy the same complications reappeared. It was, therefore, stopped permanently. The pressure sores on the sacrum and gluteal regions previously noted had failed to heal. He was readmitted for further study.

Physical examination revealed that there were numerous, red, small, crusted papules and comedones located over the back and chest. The hands, feet and lower legs were covered with small and large purpuric spots of varying ages. The eyelids were red and slightly swollen, and there was acrimation. The nose was crusted, and there was oozing about the external nares. The right radial artery showed a barely perceptible pulsation, but there was vigorous pulsation in a collateral vessel on the dorsum of the wrist. Many coarse dry rales were heard over the lung fields, and there were ill-defined areas of diminished intensity of breath sounds. The blood pressure was 14 systolic, 90 diastolic. The remainder of the examination was either unchanged or negative.

The blood showed a hemoglobin concentration of 80 per cent, with a white-cell count of 18,900 and a differential count as follows: polymorphonuclears 31 per cent, lymphocytes 20 per cent, monocytes 1 per cent, eosinophils 47 per cent and basophils 1 per cent, the red cells appeared normal. The serum nonprotein nitrogen was 30 mg per 100 cc. He ran a normal temperature throughout his hospital stay of five days. The pulse was slightly elevated.

Final Admission (three months later) The patient was fairly well after discharge. He gained 10 pounds and felt generally stronger, although he had several asthmatic attacks. About two and a half months after discharge he had a transient right hemiparesis with aphasia and convulsions. This recurred a few days later. In each instance there was complete return of muscle control. One week before entry he was examined by his physician and a urinous breath was noted. There were bilateral papilledema, exudates and hemorrhages in

the eye grounds. The blood pressure had risen to 240 systolic, 160 diastolic, and the nonprotein nitrogen was 50 mg per 100 cc. The urine showed a large trace of albumin, with a specific gravity of 1.010 and many red and white cells in the sediment. He was admitted to the hospital for terminal care and died on the second hospital day. The temperature was 99°F., the pulse 90, and the respirations 20. A lumbar puncture showed an initial pressure of 340 mm of water, and the spinal fluid gave a total protein of 40 mg per 100 cc., no cells were observed.

DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG It seems to me that the outstanding features of the story were the asthma which this man had had for about six years before his final illness, the persistently high eosinophilic count in the blood, the weight loss, the cachexia, the purpura and finally the fairly rapid development of hypertension and signs and symptoms of acute nephritis and renal failure. In addition, he also had pain in the extremities and joints, pain in the abdomen, and later central nervous-system symptoms with hemiparesis, aphasia and convulsions. I believe that if we are going to explain this story on one basis we must make a diagnosis of extensive vascular disease of some sort, but it might be worth while to see if there are any other conditions that might fit the picture.

In any individual who has a high eosinophilic count in the peripheral blood one thinks of trichinosis as a possible diagnosis, but there is absolutely nothing else in this history to make me think of it. This man had pain in the extremities but there is no note that he had muscle tenderness or that he had the swollen eyelids, the hemorrhages in the ocular muscles so frequently seen in this condition, or any history of eating infected pork. One does occasionally see high degrees of eosinophilia in Hodgkin's disease, but again there is nothing in this history to allow one to make such a diagnosis.

One other possibility would be the presence of a leukemia, and yet the blood examination seems to me to have shown nothing that would permit one to consider this condition here.

There is a disease with which we have become increasingly familiar in the past few years,—in fact I have seen other cases very much like this one,—namely periantarctic nodosa. It is quite interesting that Rackemann and Greene¹ have described a series of cases in which asthma was a part of the disease. They reported 8 cases of their own all of which showed a high degree of eosinophilia. Asthma had been present from two

to twenty-seven years before the periarteritis could be diagnosed. We have no way of knowing whether it was present for all that time and in what way the asthma was associated. In addition to these 8 cases they found 27 others in the literature in which asthma and periarteritis had been present at the same time. The pathologic lesions in this disease are primarily vascular—perivascular infiltration with eosinophils, with involvement of the intima and thrombosis of numerous vessels, very often with the formation of small nodules and aneurysms. This may occur in small blood vessels anywhere, and on that basis, symptoms may occur in any system. One previous case that we saw here was erroneously diagnosed trichinosis because of severe pain in the arms and legs. A muscle biopsy was made which established the diagnosis. That patient lived six years after leaving the hospital.

The involvement of the various organs in periarteritis nodosa is of some interest. According to the literature^{2,3} the kidneys are involved in 80 per cent, the heart in 70 per cent, the liver in 65 per cent, the gastrointestinal tract in 50 per cent, the muscles in 30 per cent, the peripheral nerves in 20 per cent and the central nervous system in 8 per cent. Lesions of the most varied sort may take place. A group of cases has been reported² from the Mount Sinai Hospital in New York City, in which patients came in with abdominal pain suggesting appendicitis. The appendix was removed and found to contain thrombosed vessels due to periarteritis.

The eosinophilia which occurred in this case is by no means a common phenomenon in this disease. It so happens that most of the cases I have seen had eosinophilia, but in reported cases in the literature it occurred in 12 per cent. Usually there is a leukocytosis with a predominance of polymorphonuclear cells. A fairly severe secondary anemia is the rule. Many of the patients have hypertension. It is remarkable that more do not have hypertension when one considers the extensive vascular involvement that these patients may have, as well as the renal involvement. Neurologic manifestations may be extremely varied in their symptomatology, peripheral neuritis is not uncommon. The case which I described in which we erroneously made the diagnosis of trichinosis had extensive signs of peripheral neuritis, which when present is due to the same cause that produces symptoms in other systems, namely thrombosis of the small blood vessels, in this case the nutrient arteries of the peripheral nerves. So far as the central nervous system is concerned, almost any lesion may appear.⁴ These patients very

often run a fever. We have seen cases with low grade fevers—up to 100 or 102°F—persisting for many months. The signs and symptoms of coronary thrombosis may occur, and signs of renal failure, as in this case, are not uncommon.

There is one interesting point in this history—the blood Hinton test was negative. That is of interest because in some of the early cases syphilis was suspected as the etiologic agent inasmuch as there was aneurysmal dilatation in some of the vessels. A few cases were treated with arsphenamine, but not with any striking success.

The mortality in cases of periarteritis nodosa is extremely high. In the series of reported cases, now over 200, the mortality rates run between 90 and 95 per cent. I know of two patients who lived five or six years after the diagnosis was definitely made, and one continued to have rather severe asthma during that time. There has been a good deal of speculation about the cause of the eosinophilia, and it appears that the high eosinophilic count occurred rather regularly in those individuals who had asthma as a striking feature of the disease. Others have believed that the asthma was not sufficient to account for it. Some would explain eosinophilia in periarteritis on the basis of marked muscle degeneration. The muscles are involved in 30 per cent, and I do not believe this an entirely adequate explanation of the eosinophilia.

Another interesting observation by authors who have reported these cases was a very frequent history of sepsis shortly preceding the onset, and that was true here. This man had had severe sinus infection. Many organisms have been found to be associated with the disease, quite often the streptococcus. Others have claimed that there was a relation between this disease and rheumatic fever, but I do not believe it has been proved in any sense of the word. The general impression at the present time is that the etiology is unknown, but that there may be a sensitivity to the streptococcus or some of its toxic products. I think in one case someone succeeded in reproducing the disease in animals which he had sensitized with streptococci.

I shall make a diagnosis of periarteritis nodosa, which seems to me the only one on which one can explain the symptoms that were present in almost every system of the body, and I shall predict that he had fairly severe nephritis due to vascular changes—that probably being the reason for the sudden marked rise in the blood pressure—and central-nervous-system changes on the basis of small thromboses. There was probably also a fairly large perirenal hematoma. Hematomas of all sorts

are described extensively in this disease. One more point is that skin lesions occur in 15 per cent of the cases—nodules, purpura, rashes and actual necrosis occur. The fact that the pressure sores did not heal may mean that there were vascular lesions in association with them. However, the skin lesions in the presence of the swollen eyes and oozing nose may of course have been due to sodium.

DR. J. H. MEANS: Was a biopsy performed on the skin nodules?

DR. TRACY B. MALLORY: One was removed and proved to be something entirely inconsequential, a small fibroma. Have you any comments to make, Dr. Lyons?

DR. CHAMBERLAIN LYONS: Nothing, except to say that he was referred to me for study of a bacterial infection, the diagnosis of periarteritis nodosa was so obvious that even I made it right off and passed him on to the medical service.

DR. SEDGWICK MEADE: Do any of the cases with neurologic manifestations have subarachnoid hemorrhage?

DR. LUDWIG: Yes, one man with asthma and periarteritis, who is still living, came in here with a subarachnoid hemorrhage as the presenting symptom.

CLINICAL DIAGNOSIS

Periarteritis nodosa

DR. LUDWIG'S DIAGNOSIS

Periarteritis nodosa

ANATOMICAL DIAGNOSES

Periarteritis nodosa.

Cardiac hypertrophy, hypertensive type.

Endocarditis, healed, aortic valve (? rheumatic)

Arteriosclerosis, moderate, aorta and coronary arteries

Pulmonary emphysema, slight.

PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Ludwig's diagnosis is correct. The only thing that one can be sure of in regard to cases of periarteritis nodosa is that no two of them will be alike. There is an infinite variation in clinical symptoms and anatomical findings because the process can be exaggerated in one system of the body and be entirely lacking in another. In this case the point of maximal involvement at the postmortem examination was unquestionably the kidneys. There was very severe disease of the large and medium sized arteries of the kidney. Throughout this case the lesions affected rather larger arteries than usual,

judging from our personal experience. The terminal arterioles are almost never involved, nor are the large arteries. The large arterioles and the very small arteries ordinarily show the maximal involvement, vessels just at the borderline of macroscopic visibility. In this case the lesions were most numerous in readily visible vessels from 1 to 2 mm in diameter. There had been very extensive destruction of the renal parenchyma, although the kidneys were still swollen rather than atrophic.

The heart weighed 500 gm., I believe as a result of the hypertension. The coronary arteries showed quite extensive atheroma of the major branches and very occasional periartheritic lesions of the small branches. These tended to be concentrated in the vessels supplying the right auricle, where several small thrombosed arteriolar aneurysms were found, which were around 1 or 2 mm in diameter. There was evidence of old endocarditis of the aortic valve, with fusion of two of the cusps. This seemed inactive, and we thought that it had nothing to do with the major process. The lungs were negative, and very scattered lesions were found elsewhere, except in the brain where once again there was considerable involvement with two quite definite gross infarcts in the basal nuclei. The great majority of the lesions were in an inactive state. Aneurysms had formed, the aneurysms had thrombosed, and the thrombi had undergone organization. It is, I think, quite possible that if the severe hypertension had not developed this man would have survived the acute stage of the disease and might have lived a number of years.

DR. ROBERT S. PALMER: What is the incidence of hypertension in the reported cases or the ones seen here?

DR. LUDWIG: So far as I know, no standard incidence has been given.

DR. MALLORY: An occasional case presents itself as one of malignant hypertension. The first case I ever saw was one of that type.

DR. CHESTER M. JONES: The cases we have seen here, as I recall, have at first been frequently diagnosed or considered peripheral neuritis or rheumatoid arthritis. I should like to know whether there have been any lesions found in the joints themselves. Have they been reported?

DR. LUDWIG: I did not find any such reports.

Was any peripheral-nerve change demonstrated histologically?

DR. MALLORY: It has been quite extensive in many cases. In this case we had sections of several nerves but found none.

DR. JONES: There is one patient that Dr. Rackemann and I saw who died apparently of heart failure plus very bad asthma and at autopsy, as

I remember, the bronchi were quite occluded by the mucus usually found in asthma

DR. MALLORY In this case there was a considerable amount of mucus in the smaller bronchioles, what one might well find in a chronic asthmatic patient between paroxysms, but not the extensive plugging that one finds with paroxysmal death

DR. LUDWIG The diagnosis is usually made by biopsy?

DR. MALLORY Yes, it almost always is

DR. JONES Abdominal pain can be excruciating at times, almost as severe as renal colic

DR. LUDWIG In one case described in the Mt Sinai group, the patient had thrombosis of the portal vein, furthermore, thrombosis of the mesenteric vessels is quite common

CASE 26192

PRESENTATION OF CASE

A seventy-eight-year-old American physician entered the hospital complaining of abdominal distention, cramps and diarrhea

The patient had had no abdominal difficulty until approximately two and a half years before admission, when he experienced vague and diffuse abdominal pains which were rather discomforting but not crampy. These were associated with some diarrhea, and believing them to be due to a colitis, he took some medicine, which apparently relieved all his discomfort during the next few months. Since then he had had three or four similar attacks, each lasting two to four months, and each associated with shifting abdominal pains and diarrhea. Two months before entry he began having crampy abdominal pain, intermittent in character and lasting a few seconds at a time. The abdomen would become distended and definite peristaltic waves could be seen. Distention usually came on toward evening and was accompanied by cramps. Attacks occasionally came on at night, waking the patient. He continued to have diarrhea, usually four to seven stools a day, which often relieved the marked distention. As a rule the stools were watery to mushy and brown, without any blood. He passed a moderate amount of gas by rectum. During this two-month period he vomited about five or six times, the vomitus being green and

very sour. He believed he had lost some weight but did not know how much. His strength was fair until about two weeks previous to entry. His appetite was good.

The family and past histories were not contributory.

Physical examination showed a well-developed man who did not appear acutely ill. The chest was barrel shaped and symmetrical, and showed fair expansion. The heart seemed to be slightly enlarged to the left by percussion. The abdomen was markedly distended and tympanitic, and numerous peristaltic waves were observed. There was marked borborygmus, but no tenderness or definite masses. The prostate was moderately enlarged and symmetrical. The blood pressure was 142 systolic, 80 diastolic.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red-cell count of 4,940,000, 141 gm of hemoglobin and a white-cell count of 7200 with 57 per cent polymorphonuclears. The stools were brown, and guaiac negative. A plain roentgenogram of the abdomen showed numerous dilated, gas-filled loops of small bowel and a moderate amount of gas in the transverse colon and in the region of the splenic flexure. Films taken in the upright position showed numerous fluid levels in the small intestine. A barium enema flowed to the cecum without delay, the colon was normal in position and mobility. The tip of the cecum was directed anterolaterally. In the region of the ileocecal valve there was a considerable area of narrowing and deformity which did not change during the examination. After evacuation the films showed this area to be still present. At no time was barium seen to enter the terminal ileum. Spot films of this area suggested the presence of mucosal folds passing through the area of narrowing.

He was given large amounts of intravenous glucose, and on the fifth day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. HORATIO ROGERS May I see the x-ray films?

DR. AUBREY O HAMPTON There are sets of plain films on two succeeding days, and at both times there is obvious evidence of small bowel obstruction. You can see dilated loops in both, but they are much more marked on the second day. There are fluid levels in the small bowel when the patient is upright. A barium enema shows a quite unusual defect in the cecum. It appears to be due to pressure from without, and yet the mass is quite intimate with the cecum.

You cannot separate the mass from the bowel. It is present in all films. There is another defect in the ileum, but the ileal mucosa appears normal. There is no real intussusception, yet the ileum points toward the cecum as though it were trying to intussuscept. The lumen of the ileum remains very narrow in all the films.

DR. ROGERS: What is meant by the statement, "The tip of the cecum was directed anterolaterally"?

DR. HAMPTON: I cannot prove it, but the cecum appears to be projected on end. It should go straight toward the pelvis. It has been displaced upward and anteriorly in some manner. In this spot film it looks as though there might be some thing in the wall of the cecum. In fact, on one side the defect looks like that due to carcinoma of the cecum, whereas on the other side it looks like that due to extrinsic pressure. In none of the other films does it look like a carcinoma of the cecum. I do not know whether I have made the picture clear. I shall conclude by saying that most of the disease here represented is extrinsic but also adherent to the ileum and cecum. The difficulty in studying the mucosa of the ileum is apparent when one notes how small the lumen is in the area of the mass.

DR. ROGERS: From the history we have a seventy-eight year-old man with a two-and-a-half year history of attacks of abdominal discomfort and diarrhea without blood and a two-month history of progressive intestinal obstruction, yet on admission he was not very ill and was ready for operation five days later. From physical examination we get confirmation of the fact that he was not very ill, and of obvious small-bowel obstruction. We also learn that there was no palpable mass. From blood studies we find that he had a practically normal red-cell count and no leukocytosis. X-ray examination revealed the facts that there was a pathologic lesion in the ileocecal region and that this probably originated outside the bowel.

We know that he had small bowel obstruction. The question is: What is the cause of the obstruction? There are three categories of causes that we must consider—mechanical, neoplastic and infectious.

Mechanical causes would include internal hernias, of which retroileal hernia is perhaps the commonest. The sigmoid colon rather than the cecum is the commonest area to show volvulus, and with volvulus I should expect the symptoms to be more acute. Intussusception is commonest in the ileocecal region, but bleeding is usually present and the x-ray picture should be more charac-

teristic. I think we can rule out a mechanical lesion as the cause of this condition.

In considering neoplasms, cancer of the cecum is by all odds the most likely. It cannot be that in this case, however, without being extremely atypical. Cancer of the cecum is characterized by rectal bleeding and by anemia. It could produce the diarrhea that this patient complained of, but by the time it had reached the size to give this x-ray picture it should have given anemia, some degree of cachexia and a palpable abdominal mass. I think we can safely rule out cancer of the cecum. Of the benign tumors of the cecum perhaps polyp is the only one to be considered, but not seriously. It might be a lipoma or carcinoid in the terminal ileum, but there is no evidence that this is a tumor of the small intestine, and there is a good deal of evidence from the x-ray films that it is not.

Chronic infections or the late results of acute infections must be considered. There is the hypertrophic type of tuberculosis of the cecum, which is characterized by diarrhea, usually with bleeding, and a destructive process which would be capable of producing small-bowel obstruction as a late result. But since it is usually accompanied by signs of tuberculosis elsewhere and rarely occurs in patients over forty, I do not believe we can consider it here. Regional ileitis is characterized by a long-continued diarrhea without bleeding and a certain degree of fever, debility and wasting, but that also is a disease of young adults, and the x-ray films, which should be characteristic, do not in the slightest suggest it in this case. We can dismiss chronic ulcerative colitis at once, because that is also a disease of young adult life which is characterized by diarrhea and bleeding and presents a typical picture in the colon by x-ray. Also, in ulcerative colitis the rectum is usually involved in the later stages, and in this case nothing is said about that. Diverticulitis is a disease which a man of this age could well have, but it usually occurs in the sigmoid, furthermore, the diverticula are usually multiple, and nothing is mentioned about them in the x-ray films of this patient.

This leads us to the conclusion that we are dealing with some benign condition—either a very unfamiliar one or a common one in unfamiliar guise. We must not forget that by all odds the commonest inflammatory disease of the abdomen is appendicitis and that at this age the symptomatology of appendicitis may be very atypical, the tendency being for a minimization of the symptoms, which are so clear in a younger patient. In spite of too much diarrhea and too little in the way of acute symptoms, this patient could have

had acute appendicitis two and a half years ago. He could have had a recurrence of it on several occasions afterward, with, at some time, abscess formation, absorption of the abscess and quieting down of the acute infection, and he could have been left with a great deal of scar tissue and dense adhesions around the cecum and terminal ileum—a condition which could produce this x-ray picture and result in obstruction of the terminal ileum without leukocytosis. I think that is what he had, and I am certain that the surgeon who operated on him was puzzled by what he found and that even possibly the pathologist was doubtful when he first saw the specimen.

DR F DENNETTE ADAMS: Dr Rogers may have been slightly misled by the history of the early part of this man's illness. The chief complaint was diarrhea. The episodes of pain which he had were not remarkable, as I obtained his history. There was no especially acute episode of pain until he began to get into trouble two and a half months before he was operated on.

DR ROGERS: Yes, that is the risk I am taking, if I am wrong, I expect to be very thoroughly wrong.

PREOPERATIVE DIAGNOSIS

Intestinal obstruction from carcinoma of cecum

DR. ROGERS'S DIAGNOSIS

Ileocecal obstruction from old appendiceal abscess

ANATOMICAL DIAGNOSIS

Carcinoid of the ileum

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: Dr Rogers was wrong in two of his predictions: the case was not one

of appendicitis, and we do know what it was. The patient was operated on in two stages. At the first operation a mass was found in the region of the cecum and an anastomosis was done around it. I was called over at the time of the second operation and examined the specimen in the operating room. On opening the cecum and terminal ileum the mucosa of both was perfectly intact. There was no ulceration, but there was an obvious tumor mass that could be felt in the walls. Cutting through the mass showed it to be very firm tumor with about the texture and pattern of a fibroid of the uterus, except that it was bright orange-brown. The color reminded me immediately of adrenal tissue, but a frozen section showed that it was a carcinoid.

These are relatively rare tumors, yet this is the third that we have had in a very short period. The tumor primarily involved the ileocecal valve, with extension to both the ileum and cecum. The major portion was external to the bowel wall, however, and most of the x-ray deformity was produced by pressure of the external tumor.

DR. ROGERS: Is it not less common in the large than in the small intestine?

DR MALLORY: The commonest site of carcinoid tumors is the appendix, the next is the terminal ileum, and we have seen one case which we believe to be carcinoid of the rectum. They have been reported all the way from the stomach to the rectum, but the appendix and the lower ileum are the only common places.

A PHYSICIAN: How do you account for diarrhea being a presenting symptom?

DR MALLORY: I cannot account for it except that lesions in that area very frequently cause diarrhea, it seems to make no difference what the lesion is.

HOSPITAL DAY

EIGHTEEN years ago Mathew Foley then editor of *Hospital Management* suggested that it would be appropriate to celebrate May 12, the birthday of Florence Nightingale, as Hospital Day. This original idea was warmly received, and Hospital Day has become generally accepted as the day on which hospitals are annually brought to public notice. It is appropriate, therefore, to consider at this time some of the problems that hospitals are facing.

Of late there has been much discussion of the relative merits of voluntary or non-governmental and tax-supported or governmental hospitals. Some enthusiastic supporters of "state medicine" have advocated the assumption by government of all medical activities, including the support and direction of hospitals. The place of voluntary hos-

pitals in the medical structure has been most ably set forth by Mr. A. V. J. Hinds,* of Liverpool, England, in a booklet entitled, *Hospital Testament*.

Mr. Hinds points out that there are arguments supporting both the voluntary and the tax supported hospitals, but that since the voluntary hospitals are doing their work efficiently and since taking over by governmental agencies would require a tremendous initial cost—unless confiscation were resorted to—and a continuing high operating cost, both of which would result in increased taxation, there is slight chance of serious consideration of such a step.

Furthermore, Mr. Hinds writes

It is clear that hitherto the voluntary hospitals have always attracted to themselves the most brilliant medical men. The merit of their organization is that they do in fact create rather than attract the best men. The width of experience available to the Honorary engaged partly in private practice and partly in hospital work has already been emphasized but there is an important aspect of it that needs elaboration. The Honorary work for the hospital as doctor, teacher and research worker must be maintained at the high standard which is necessary to provide him an income in his private practice. If the quality of his hospital work deteriorates his reputation is damaged and his private practice suffers. He thus has a constant incentive to achieve distinction which would be lacking if he were a salaried officer of the hospital, an incentive to give of his best to his hospital work—which is a public service—in order to benefit his private work which is his livelihood. Furthermore, his eminence in his profession is maintained only by the confidence of those he serves, and the persons who have the greatest say in giving him employment as a consultant in a private case are the general practitioners, members of his own profession who are judging him as expert.

Mr. Hinds believes sentiment alone is not sufficient to justify the continuation of voluntary hospitals. Therefore, he submits the following scientific arguments

1. The voluntary hospitals ensure that only the best brains of the medical profession are accorded distinction by subjecting them to the rigorous test of recognition by their practicing colleagues engaged in the same work in the same profession. They do not obtain positions of eminence as a result of selection and promotion decided solely by a political body or a lay administrator.

2. The voluntary hospitals ensure that the best brains of the medical profession are not only at the command of the wealthy but are also at the service of the public as practitioners in the hospitals. The benefits of first rate medical attention are not confined to one class of the community.

*Hinds, A. V. J., *Hospital Testament*. London: Hodder and Stoughton, Ltd. 1939.

3 The voluntary hospitals ensure that the best brains of the medical profession are not only engaged in the practice of medicine but are also at the disposal of the public as university teachers of medicine. There is no separation of the practical work from the teaching of it.

4 The voluntary hospitals ensure that for the performance of these public services the medical profession is remunerated, not by fixed salary, but indirectly by the rewards of private practice, in such a way, therefore, as to provide the maximum incentive for the achievement of excellence. There is no danger that a hospital appointment or a teaching appointment will be regarded as a sinecure.

5 The voluntary hospitals ensure that the teaching of medicine in the universities, and research into new methods of treatment in the hospitals, are guided and controlled by independent laymen whose loyalty to a single purpose permits and inspires them to provide the funds required for a bold policy of advancement in research. There is not the necessity to confine expenditure along the lines imposed by direct responsibility to the masses of the public.

6 The voluntary hospitals ensure that in one of the most important spheres of social life there is a variety of approach, on the one hand by public bodies, and on the other by private and voluntary institutions. The existence side by side of the two types of effort affords a useful basis of contrast, and a stimulus to friendly and healthy rivalry. Experiment of every kind is easier for the private and voluntary agency, but both types benefit from the results of research which proves itself successful.

There is a great similarity between the hospital systems of Great Britain and of the United States. Mr. Hinds's conclusions, therefore, may be applied aptly to the situation here, and Hospital Day seems to be a proper time to emphasize that there is work enough in this country for both voluntary and governmental hospitals and that the future of each lies not in competition but rather in co-operation with the other.

THE COMMERCIAL EXHIBITS

OF the sixty-five commercial exhibits that are scheduled for the annual meeting of the Massachusetts Medical Society this year, some have been arranged by old friends and others by newcomers. All exhibitors have gone to considerable trouble and expense to present attractive booths, which should be visited by the members of the Society for the purpose not only of gaining information but also of expressing appreciation for co-operation.

Few realize the extent of the financial support given to the Society by the exhibitors. This year

these firms are contributing more money than ever before for booth space and are thereby making it possible for the Society to continue the annual meetings at their present size without their becoming a financial drain. Furthermore, many of them support the *New England Journal of Medicine* by their advertising. The officers of the Society and of the *Journal* appreciate and value this support, but they realize that it will continue only so long as there is interest by the members in the products of these firms.

Every member of the Society who attends the annual meeting should take time to visit the various exhibits, and if he remembers the firm as an advertiser in the *Journal*, he should comment on that fact. Such interest will be well repaid by the exhibitors in their loyalty to the Society.

MEDICAL EPONYM

BROADBENT'S SIGN

Credit for the discovery of this sign must be given to Sir William Broadbent (1835-1907), although it was first described by his son, Walter Broadbent, in an article entitled "An Unpublished Physical Sign," which appeared in the *Lancet* (2200, 1895). Later in 1895 an elder son, John F. H. Broadbent, now Sir John, included a description of the sign in his book *Adherent Pericardium* (London, 1895). It was not until 1898 that Sir William published his description, which appears under the title "Adherent Pericardium" in the *Transactions of the Medical Society of London* (21: 109-122, 1898).

A systolic tug of the left false ribs posteriorly communicated by the diaphragm may be conspicuous. The recoil from the drag may be so distinct as to look and feel to the hand like pulsation, and in the first case in which I observed it, now more than twenty years since—a case of left empyema—it was taken for pulsation, and it was supposed that a pulsating tumour of some kind underlay the empyema. A *post-mortem* examination showed that the cause was adherent pericardium. I have often seen this tugging since, and in some cases it can be made to affect the right false ribs by causing the patient in the sitting position to lean over to the left so as to throw the drag of the heart upon the right half of the diaphragm. It must be added that this indication is not infallible, as the tugging has been observed when the heart was hypertrophied without adhesions.

R. W. B.

MASSACHUSETTS MEDICAL SOCIETY

ANNUAL MEETING OF THE COUNCIL

The annual meeting of the Council will be held in the Swiss Room of the Copley Plaza, Boston, Tuesday, May 21, at 10.30 a.m.

BUSINESS

- 1 Presentation of record of meeting held February 7, 1940, as published in the *New England Journal of Medicine* for March 7, 1940
- 2 Nominating Committee retires to deliberate.
- 3 Reports of standing and special committees.
- 4 Election of officers and orator
- 5 Appointment of committees for ensuing year, both standing and special.
- 6 Incidental business.

ALEXANDER S. BEGG *Secretary*

Councillors are asked to sign one of the two attendance slips before the meeting. The Cotting Luncheon will be served immediately after the meeting

PYELITIS DURING PREGNANCY

Mrs. T., a twenty-six year-old para II, about twenty weeks pregnant, complained on November 6, 1912, of fatigue and fever. The temperature was 103°F., there was some urinary irritation.

The family history was negative. The patient had had infection of the mastoid as a child, and an abscess under conservative treatment burst externally. At the age of six she had had a period of unexplained fever lasting six to eight weeks. She had also had measles, and although intimately exposed, had never had scarlet fever. At the age of twenty-one she had had an attack of acute sinusitis, followed by a mild attack of rheumatic fever, the latter lasted about six weeks and left no sequelae. She had never undergone a surgical operation. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted five days with no discomfort. The last period was June 8, making the expected date of confinement March 15, 1913. The previous pregnancy had been normal throughout.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

She was first seen on August 12, at which time physical examination showed a well-developed and well-nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The blood pressure was 112 systolic, 60 diastolic. The breasts showed engorgement. The abdomen was normal. The uterus was anterior, and enlarged consistent with the period of amenorrhea. Examination of the extremities was negative, as was that of the urine.

The pregnancy was normal until November 6. At that time the urinary sediment contained a large amount of pus and the right kidney was definitely tender. A diagnosis of pyelitis was made, and conservative medical treatment was instituted—forced fluids, urotropin and sodium bicarbonate. The temperature ran an up-and-down course for ten days and then remained normal for about a week. Following no apparent in discretion the patient had a chill and the temperature rose abruptly to 103°F., with a pulse of 120. There was again much pus in the urine, and the patient had a great deal of bladder irritation. The attack lasted for about ten days, and then the temperature reached normal and remained so for another week. Another attack, similar to the two previous ones, followed. This time, as was very often done when the bladder showed marked irritation, a consulting urologist recommended that the bladder be irrigated with warm boric acid solution, however, no relief was obtained. These various attacks were accompanied by chills, general malaise, lack of appetite and marked despondency. The last one occurred six weeks before delivery. The pregnancy from then on showed no exacerbation of the pyelitis, and the baby was born on March 12, 1913, after a short normal labor.

Comment. This case illustrates the treatment of pyelitis of pregnancy at a time when it was entirely symptomatic and supportive. Nowadays bladder lavage is never considered. The subsequent history offers justification for the good prognosis that was offered patients suffering from pyelitis of pregnancy at that time. Since then the patient has had one other child, the pregnancy being complicated by pneumonia at seven months, has undergone an operation for intestinal obstruction and has had frequent gallstone attacks, but has never had subsequent attacks of pyelitis. Today at the age of fifty-four the blood pressure is 116 systolic, 60 diastolic, and the urine is normal.

MASSACHUSETTS MEDICAL SOCIETY

THE ONE HUNDRED AND FIFTY-NINTH ANNIVERSARY

Tuesday and Wednesday, May 21 and 22, Copley Plaza Hotel, Boston

The exercises of the one hundred and fifty-ninth annual meeting of the Society will be held at the Copley Plaza Hotel, Boston, on May 21 and 22. Members of the medical profession are invited to attend.

The Committee of Arrangements in charge of this year's meeting consists of Drs. Augustus Thorndike Jr., chairman, Edward J. O'Brien, William T. O'Halloran, James A. J. Foster and George P. Sturgis.

With the exception of some of the section round-table meetings and luncheons, all the meetings will be held in the Copley Plaza Hotel. The commercial exhibits will fill the ballroom and part of the foyer while the unusually interesting scientific exhibits will take the balance of the foyer, the balcony boxes and the east corridor of the main floor. At the end of the east corridor will be a continuous moving-picture exhibit of medical pictures. The program has been selected with care and contains a number of pictures made by members of the Society which should prove interesting and instructive.

The members' registration desk will be in the main ball room, and it is hoped that everyone who attends will register.

The annual dinner and the Shattuck Lecture will be held on the same evening Tuesday May 21.

The golf tournament will be held at the Belmont Country Club on Tuesday May 21.

Section round-table meetings and luncheons will take the place of the section meetings of other years. As it is necessary to have beforehand some idea of the number who will attend these luncheons, all members are urged to notify the committee at once if they plan to come.

TUESDAY MAY 21

General Clinical Meeting

9:00 to 12:00

SHERATON ROOM

Chairman Dr. A. Warren Stearns

9:20 *Tumors of the Breast* Dr. Grantley W. Taylor, Boston.

9:35 Discussion by Dr. Shields Warren, Boston.

9:45 *Treatment of Prostatic Obstruction* Dr. Reed Nesbit, Ann Arbor, Michigan.

10:15 Discussion by Dr. William C. Quinby and Dr. Fletcher H. Colby, Boston.

10:25 *Acute Surgical Emergencies of the Abdomen in Pregnancy* Dr. Judson A. Smith and Dr. Marshall K. Bartlett, Boston.

10:40 Discussion by Dr. Howard M. Clute, Boston.

INTERMISSION

11:00 *The Relation of Urinary-Tract Infections to Hypertension* Dr. Soma Weiss, Boston.

11:15 Discussion by Dr. Allan M. Butler and Dr. Robert S. Palmer, Boston.

11:25 *The Treatment and End Results of Plantar Warts* Dr. Joseph H. Marks and Dr. Clifford C. Francis, Boston.11:35 *The Diagnosis of Marie-Strümpell Arthritis with Certain Aspects of Treatment* Dr. Hugh F. Hare, Boston.

11:50 Discussion by Dr. Charles L. Short, Boston.

Supervising Censors Meeting (PARLOR A) 10:00

Council Meeting (SWISS ROOM) 10:30

Nominating Committee (PARLOR A)

Cotting Luncheon (SWISS ROOM) 1:00
(following Council Meeting)Section Round Table Meetings and Luncheons
12:00 to 2:00

All round-table luncheons will be \$1.00. Reservations should be made at once.

Section of Medicine

PRESIDENT'S ROOM, UNIVERSITY CLUB

Chairman Dr. Chester M. Jones, Boston.

Secretary Dr. Erwin C. Miller, Worcester.

Subject *Toxic Manifestations of Important Drugs*

Section of Obstetrics and Gynecology

MAIN DINING ROOM, UNIVERSITY CLUB

Chairman Dr. Roy J. Heffernan, Brookline.

Secretary Dr. Raymond S. Titus, Boston.

Subject *Abnormal Uterine Bleeding* Leader Dr. Frank A. Pemberton, Boston, assisted by Drs. Thomas Almy, Fall River; Robert J. Carpenter, North Adams; and Joel M. Melick, Worcester.

Section of Surgery

CRYSTAL ROOM, WESTMINSTER HOTEL

Chairman Dr. Reginald H. Smithwick, Boston.

Secretary Dr. Bancroft C. Wheeler, Worcester.

Subject *Vitamins and Surgery*

Section of Pediatrics

BALLROOM, WESTMINSTER HOTEL

Chairman Dr Charles F McKhann, Boston

Secretary Dr James M. Baty, Boston

Subject *Allergy in Childhood*

Section of Dermatology and Syphilology

STATE SALON, COPLEY-PLAZA HOTEL

Chairman Dr C Guy Lane, Boston

Secretary Dr John G Downing, Boston

Subject *Skin Manifestations on Extremities*

General Clinical Meeting

2 00 to 5 00

SHERATON ROOM

Chairman Dr William H Robey

2 00 *The Common Cold* Dr Wilson G Smillie, New York City

2 20 Discussion by Dr Arlie V Bock, Cambridge

2 30 *The Relation of Sinus Infection to Chronic Non-Tuberculous Pulmonary Infection* Dr Robert L. Goodale, Boston.

2 45 Discussion by Dr Charles F McKhann and Dr Philip E. Meltzer, Boston.

2 55 *The Surgical Treatment of Chronic Lung Abscess* Dr Edward D Churchill, Boston

3 10 Discussion by Dr Thomas H Lanman and Dr John W Strieder, Boston

INTERMISSION

3 30 *Tuberculosis in Childhood* Dr Edith M Lincoln, New York City3 50 *The Pathogenesis of Primary and Reinfection Types of Pulmonary Tuberculosis* Dr Esmond R. Long, Philadelphia

4 10 Discussion by Dr Henry D Chadwick, Newton.

4 20 *The Treatment of Pneumococcal Pneumonia* Dr Francis G Blake, New Haven, Connecticut.

4 50 Discussion by Dr Kenneth D Blackfan and Dr Donald S King, Boston

Annual Dinner (MAIN DINING ROOM) 7 00

The Shattuck Lecture (SHERATON ROOM) 8 45

Immunity to Virus Diseases Some theoretical and practical considerations Dr Ernest W Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tennessee

WEDNESDAY, MAY 22

Symposium on Syphilis

9 00 to 11 00

SHERATON ROOM

Chairman Dr C Guy Lane

9 00 *The Clinical Manifestations of Primary Syphilis* Dr Francis M. Thurmon, Boston.9 15 *The Interpretation and Reliability of Reports of Serologic Tests for Syphilis* Dr Tracy B Malory, Boston.9 30 *The Detection and Treatment of Cardiovascular Syphilis* Dr Herrman L Blumgart, Boston.9 45 *The Early Clinical and Laboratory Manifestations of Central-Nervous-System Syphilis* Dr H. Houston Merritt, Boston.10 00 *The Public Health Aspects of Syphilis as it Concerns the General Practitioner* Dr Thomas Parran, Washington, D C

10 30 Discussion by Dr Rudolph Jacoby, Dr Austin W Cheever, Dr Howard B Sprague, Dr James B Ayer and Dr Dwight O'Hara, Boston.

Annual Meeting (SHERATON ROOM) 11 00

Annual Oration (following meeting)

New England, Neurosurgery and the Neurosurgeon Dr William Jason Mixter, Boston.

Annual Luncheon (SWISS ROOM) (following oration)

Symposium on Sulfanilamide

2 00 to 5 00

SHERATON ROOM

Chairman Dr Reginald Fitz

2 00 *The Management of Acute Streptococcal Infections of the Upper Respiratory Tract* Dr Conrad Wesselhoef, Boston.

2 15 Discussion by Dr Gordon Berry, Worcester

2 25 *The Treatment of Puerperal Sepsis* Dr Joseph P Cohen, Boston.

2 40 Discussion by Dr Champ Lyons, Boston

2 50 *The Treatment of Urinary-Tract Infections by Specific Therapy* Dr E Granville Crabtree, Boston.

3 05 Discussion by Dr George Gilbert Smith and Dr Samuel N Vose, Boston.

INTERMISSION

3 30 *The Diagnosis and Treatment of Gonorrheal Arthritis* Dr Chester S Keefer, Boston.

3 45 Discussion by Dr Walter Bauer, Boston.

3 55 *The Treatment of Meningococcal Meningitis* Dr Edwin H. Place, Boston.

4 10 Discussion by Dr LeRoy D Fothergill, Boston.

4 20 *The Possible Skin Manifestations of Sulfanilamide* Dr Arthur M. Greenwood, Boston.

4 30 Summary Dr Perrin H Long, Baltimore, Maryland

Additional Exhibits

BALLROOM

Massachusetts Association of Occupational Therapy

FOYER

Central Directory for Nurses

Commercial Exhibits

BALLROOM AND FOYER

Booth

- 1 Ernst Bischoff Company, Incorporated, Ivoryton, Connecticut.

In our exhibit we shall feature Activin, the first American produced shockless foreign protein for non-specific therapy, Diatussin, the original drop-dose cough remedy with a thirty five year record of efficacy, Lobelin-Bischoff, a direct stimulant to the respiratory center and the resuscitant indicated in all forms of respiratory failure or depression, Silvogon, an absolutely stainless silver antiseptic and an effective gonocide, Styptysate, a vegetable hemostatic for the control of all seeping hemorrhages, Viscysate, a dialysate of viscum album that lowers blood pressure and relieves the accompanying symptoms

- 2 Eli Lilly and Company, Indianapolis, Indiana

Eli Lilly and Company produced the first commercial preparation of insulin, contributed to development of liver therapy, and has been responsible for many other therapeutic advancements. Information concerning all Lilly products will be available at the Lilly exhibit where Merthiolate (Sodium Ethyl Mercury Thiosalicylate, Lilly), Sodium Amytal (Sodium Isoamyl Ethyl Barbiturate, Lilly) and other important products will be featured.

- 3 Philip Morris & Company, Limited, Incorporated, New York City

Philip Morris & Company will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes. Their representative will be happy to discuss researches on this subject, and problems on the physiological effects of smoking.

- 4 M & R Dietetic Laboratories, Incorporated, Columbus, Ohio

M & R Dietetic Laboratories, Incorporated, will display Simulac, a completely modified milk for infants deprived of breast feeding. Representatives will gladly explain its merit and suggested application.

- 5 Bilhuber-Knoll Corporation, Orange, New Jersey

At this booth the use of Metrazol to overcome barbiturate or opiate poisoning, surgical shock and asphyxia can be discussed, also the advantages of Dilaudid Hydrochloride for pain relief and for cough sedation, and Theocalcin as a diuretic and myocardial stimulant. Other well-known medicinal chemicals exhibited by the Bilhuber-Knoll Corporation include Euresol, Lenigallol and Bromural. Helpful prescription information on any of these products is available.

- 6 Jones Metabolism Equipment Company, New York City

The Jones Metabolism Equipment Company invites you to see the original waterless metabolism apparatus. The exclusive features of the Jones apparatus include a double slope tracing which eliminates the possibility of technical errors, a simplified and accurate slide rule for calculations, and the life time guarantee of accuracy greater than 99 per cent. The twenty years of experience of the Jones Metabolism Equipment Company have made it possible for them to produce a fool proof, simple and accurate machine.

- 7 Kalak Water Company, New York City

Visit this booth and ask the Kalak representative to explain to you how Kalak Water may be employed as a buffer to inhibit the untoward effects and enhance the value of certain drugs.

- 8 Liebel-Flarsheim Company, Cincinnati

The Liebel-Flarsheim Company will exhibit the well known L-F short wave generators as well as the famous Bovie electrosurgical units and the Rayson therapeutic lamp. A cordial invitation is extended to visit this booth in order to inspect the new apparatus and have it demonstrated.

- 9 Doho Chemical Corporation, New York City

Auralgan acts physiologically in acute otitis media by depleting the involved tissues of their excess fluid, and does not produce traumatic chemical changes in the superficial epithelium of the drum.

- 10-11 G D Searle and Company, Chicago

The Phantascope, familiar to many New England physicians, will be on exhibition by G D Searle and Company. This ingenious device, developed by Dr George Levene of the Massachusetts Memorial Hospitals, accurately reproduces the fluoroscopic appearance of the chest, and enables the physician to view in motion the alterations in cardiac size, rhythm and contour in a variety of typical pathologic conditions.

A number of Searle representatives will be in attendance, and physicians are cordially invited to discuss with them various products of the Searle laboratories.

- 12 Mead Johnson and Company, Evansville, Indiana.

Mead Johnson and Company will not only exhibit several new products, but will show various examples of its slogan "Servamus Fidem" — "We Are Keeping The Faith."

- 13 The Macmillan Company, New York City

Four authors on the staff of the Harvard Medical School will be represented by three outstanding books of the year. Elliott Cutler and Robert Zollinger by

their *Atlas of Surgical Operations* John Homans by *Circulatory Diseases of the Extremities* Lyman G Richards by *Otolaryngology in General Practice* Also prominent in the exhibit will be William Holmes' *Bacterial Infections and Biochemistry of Disease* by Oscar and Meyer Bodansky both spring publications. Many other notable Macmillan medical works will be shown.

14. White Laboratories, Incorporated Newark, New Jersey

Information will be presented covering the field of cod-liver oil concentration and clinical data concerning the therapeutic efficacy of White's Cod-Liver Oil Concentrate in liquid, tablet and capsule form.

Informed representatives and descriptive literature, reprints and excerpts will further demonstrate cod-liver oil efficacy and will point out the contributions of White Laboratories, Incorporated, in the vitamin A and vitamin D fields.

White Laboratories, Incorporated is one of the largest users of cod-liver oil for pharmaceutical purposes in the world. All physicians are cordially invited to visit the booth.

15. Baby's Dy Dee Service, Brookline, Massachusetts.

This exhibit explains in detail the specialized equipment and methods used in sterilizing and supplying diapers to homes in Greater Boston. In its seventh year this service has relieved thousands of mothers and nurses of the daily drudgery of washing diapers and baby clothes, at the same time protecting the baby's health by scientific methods impossible at home. An economical service, devoted exclusively to the baby.

Represented by Helen Lauriat Lyman and Faye Reynolds Rand.

16. General Electric X-ray Corporation Chicago.

A portable x ray machine, an electrocardiograph and an electrosurgical unit and x ray films will be exhibited.

17. The E. L. Patch Company Stoneham Massachusetts.

The Patch Company representatives will be on hand throughout the meeting to greet physicians and to be of service in any way. The Patch Company exhibit will include Patch's Cod Liver Oil as well as the other ethical medicinal specialties made in the Patch laboratory.

18. Crosbie-Macdonald Boston.

We represent the United States Fidelity and Guaranty Company writing physician's liability insurance for members of the Massachusetts Medical Society. George H. Crosbie, Edward J. O'Neil Jr., or Arthur H. Crosbie will be on hand at all times to discuss any questions pertaining to insurance and to quote rates for your specialty. We are notaries public, and should be glad to sign and file your narcotic drug blanks.

19. Campbell X Ray Corporation Boston.

Campbell X Ray Corporation will exhibit a new type of shock proof apparatus and various new accessory equipment.

20. Arlington Chemical Company Yonkers New York.

The Arlington Chemical Company invites you to inspect its line of proteins and pollens for the diag-

nosis and treatment of allergic conditions and its new product—Aminoids. Aminoids represents a combination of amino acids and has proved of marked therapeutic value in malnutrition underweight and loss of appetite.

Dr J R. Taylor in charge of the exhibit, will be happy to answer inquiries regarding this new product also inquiries relative to hay fever asthma and so forth.

21. E. F. Mahady Company

22. The Picker X Ray Corporation, Boston.

The Picker X Ray Corporation takes pride in announcing and showing the new Century X Ray Unit—a new high in x ray design and a new low in price. The Century with its many additional and exclusive features, is the most sensational x-ray apparatus in the low-price range.

It provides for radiography and fluoroscopy in all positions from Trendelenburg to vertical. It has ample power for fast chest and gastrointestinal radiography. It is completely shockproof in every particular with flexibility power and simplified control for every diagnostic procedure, and is available with a motor-driven table if desired. It behooves the modern medical practitioner to see this Century unit.

At the Picker booth are numerous accessories of recent and outstanding design that are of special interest to the profession. Ask for bulletins and literature.

24. Horlick's Malted Milk Corporation Racine, Wisconsin.

Nourishing, digestible, appetizing—these are the three outstanding qualities for which Horlick's is famous, whether in powder or tablet form. Visit the exhibit. You will be interested in the many uses—from infancy to old age—note especially the convenience of the tablets in ulcer diets.

25. Davies, Rose and Company Limited Boston.

Members of the Massachusetts Medical Society are so well acquainted with the products of the laboratory of Davies, Rose and Company that no further explanation of their merits is really necessary. However the company trusts that you will visit its booth and give its representatives the honor of greeting you. Messrs. Fleming and Purinton will be in attendance.

26. Frederick Stearns and Company Detroit.

Doctors are cordially invited to visit our attractive booth to view and discuss outstanding contributions to medical science developed in the scientific laboratories of Frederick Stearns and Company. Information on such outstanding products as Neo-Synephrin in its various dosage forms, Appella Apple Powder Muclose, Trimax (hydrated magnesium trisulfate) vitamin products, Solution Zinc Insulin Crystals-Stearns Cyverine Hydrochloride, Gastric Mucin and other new and interesting products will be supplied by our capable representatives.

27. The Alkalol Company Taunton Massachusetts.

Alkalol is a carefully balanced solution of alkaline and saline salts and essential oils. It contains no glycerin and only a trace of alcohol. It is indicated for use on the mucous membranes and on inflamed or irritated tissues. Alkalol was first introduced to the medical profession in 1896. Since that time it has won

and retained the endorsement of thousands of physicians

Irrigol, also a product of The Alkalol Company, is an alkaline, saline douche powder. It makes a solution that is cleansing, non-irritating, non-toxic and delightfully fragrant, cooling and comforting. Physicians find it valuable for rectal enemas and ordinary colonic irrigations, as well as for routine vaginal douching. It has been on the market since 1907.

28 Westinghouse X-Ray Company, Incorporated

Westinghouse X-Ray Company, Incorporated, will exhibit for the first time in the East the new Simplex Unit.

This unit is the latest development in high powered shockproof diagnostic equipment for both vertical and horizontal fluoroscopic and radiographic work. It is economical in its space requirements and economical in use.

29-30 Burroughs Wellcome and Company, Incorporated, New York City

The Burroughs Wellcome and Company exhibit presents a representative group of fine chemicals and pharmaceutical preparations, together with new and important therapeutic agents of special interest to the medical profession.

31 The DeVilbiss Company, Toledo, Ohio

The complete DeVilbiss line of medicinal atomizers will be on display. Specially featured in the exhibit are illustrations graphically showing the superior coverage afforded by the atomizer in the application of solutions to the nose and throat. These illustrations are based on x-ray research. Copies of the illustrations for reference may be secured from Mr. E. Manning, DeVilbiss representative in charge of the display.

32. Hanovia Chemical and Manufacturing Company, Newark, New Jersey

The very latest in ultra-violet equipment will be demonstrated, including outstanding apparatus designed for use in the fields of medicine and public health. Do not fail to see our new line of self-lighting ultra-violet high pressure mercury arc lamps, short wave and ultra short wave apparatus, Sollux radiant-heat lamps and our latest development, quartz ultra-violet lamps for air sanitation.

33 Petrolagar Laboratories, Incorporated, Chicago

Petrolagar Laboratories, Incorporated, offers in addition to samples of the five types of Petrolagar, an interesting selection of descriptive literature and anatomical charts. Ask one of the Petrolagar representatives to show you the new *Habit Time* booklet. It is a welcome aid for teaching bowel regularity to patients.

34 S. M. A. Corporation, Cleveland

The S. M. A. Corporation exhibits an interesting new display, which represents a selection of its infant feeding and vitamin products. Physicians who visit this exhibit may obtain complete information, as well as samples, of S. M. A. Powder and the special milk preparations—Protein S. M. A. (Acidulated), Alerdex and Hypo-Allergic Milk.

35 John Wyeth and Brother, Incorporated, Philadelphia

Among the specialties to be presented by John Wyeth and Brother are Amphogel, Wyeth's alumina gel, the management of hyperacidity and peptic ulcers; Kaomagma, Wyeth's magma of alumina and kaolin for the absorbent treatment of diarrhea and colitis; Alulotion, ammoniated mercury with kaolin for treatment of impetigo contagiosa; Bepron, Wyeth's beef liver with iron, for the treatment of nutritional anemias; and Silver Picrate, for the convenient treatment of trichomonas vaginitis and anterior urethritis. Physicians are invited to stop at Wyeth's display.

36 The Borden Company, New York City

Full information on Biolac, the new liquid modified milk for infants, will be available at the Borden booth. Also exhibited will be other Borden products for infant feeding, notably Klim, Dryco, Beta Lactose, Mer Soule products and Borden's Irradiated Evaporated Milk.

37 Bard Parker Company, Incorporated, Danbury, Connecticut

Bard Parker will exhibit the following products: rib-back surgical blades, renewable-edge scissors, the Ortholator case for obtaining blood samples at the side, Ortholator for obtaining accurate dental radiographs, Formaldehyde Germicide and instrument tainers for the rust proof sterilization of surgical instruments.

38 The Zemmer Company, Incorporated, Pittsburgh

The Zemmer Company extends a cordial invitation to every member of the Massachusetts Medical Society to visit its exhibit where there will be display of a number of its leading pharmaceutical products.

39 Winthrop Chemical Company, Incorporated, New York City

Winthrop Chemical Company, Incorporated, extends a cordial invitation to visit its booth, where representatives will gladly discuss the latest contributions made by this firm to the medical profession.

40 Nu-Hesive, Incorporated, Leominster, Massachusetts

Nu-Hesive, Incorporated, will exhibit and demonstrate Nu-Hesive, a new principle in surgical dressings which opens up a wide possibility of new technique to the doctor.

41 Surgeons' and Physicians' Supply Company, Boston

Surgeons' and Physicians' Supply Company will display the new Complex short wave machine, the McKesson waterless metabolizer, and an interesting collection of new items many of which are not usually shown by the salesman.

42 Mellin's Food Company, Boston

Members of the Society are cordially invited to stop at the Mellin's Food booth for an exchange of views and opinions relative to the feeding of infants and regard to the preparation of nourishment for adults requiring a restricted diet, particularly in view of the recognized importance of selecting food material adapted to individual requirements.

43. The Medical Protective Company, Wheaton, Illinois.

The most exacting requirements of adequate liability protection are those of the professional liability field. The Medical Protective Company specialists in providing protection for professional men invites you to confer at its exhibit, with the representative there. He is thoroughly trained in professional liability under writing.

44. Tailby-Nason Company, Boston.

Tailby-Nason Company has reserved space for the exhibit of Nason's Palatable Cod Liver Oil, made in the company's own plants in the Lofoten Islands of Norway romantic Land of the Midnight Sun.

More and more leading physicians are relying on good cod-liver oil in all cases requiring vitamins A and D. Nason's Oil is prescribed and recommended by leading pediatricians from the Atlantic to the Pacific for its high vitamin potency and unusual palatability.

45. C. B. Fleet Company, Incorporated, Lynchburg, Va.

Phospho-Soda (Fleet) the buffered saline laxative, combines two U.S.P. salts of sodium phosphate in a stable concentrated solution of broad therapeutic range and is free from most of the disadvantages of saline laxatives.

May we remind you of—

Its ease of administration and mild after-effects.

Its wide range of action, from gentle laxative to purge.

Its rapidity (action usually within the hour)

Its effectiveness in hepatic insufficiency

Its amphoteric neutralizing quality

Its stability, miscibility and economy

Please note the new descriptive leaflet on your professional samples.

46. Gerber Products Company, Fremont, Michigan.

Ten new foods which have just been added to the Gerber foods will be on display in the Gerber booth. Copies of both the professional literature and the booklets for mothers are there for your examination and will be sent to you on request.

47. Smith Kline and French Laboratories, Philadelphia.

Smith Kline and French Laboratories, believing that many physicians dislike efforts to make them register have arranged their booth for self service.

Up-to-date information about Benzedrine Inhaler, Benzedrine Sulfate, Benzedrine Solution, Pentnucleotide, Fesol Tablets and Elixir Oxo-rate "B" Eskay's Neuro-Phosphates and Paredrine Hydrobromide with Boric Acid Ophthalmic may be obtained in convenient envelopes from literature dispensers. If additional data are desired, the representative will be glad to answer any questions.

48. E. R. Squibb and Sons, New York City

Physicians are cordially invited to visit the Squibb exhibit. The complete line of Squibb vitamin, glandular, arsenical and biological products and specialties, as well as a number of interesting new items, will be featured.

Well-informed Squibb representatives will be on hand to welcome you and to furnish any information desired on the products displayed.

49. Lederle Laboratories, Incorporated, New York City

Lederle Laboratories Incorporated, will feature a display of its hay fever poison ivy and allergic products together with globulin-modified Lederle antitoxins and selected pharmaceutical products, featuring Vi Delta Emulsion and Vitamin B Complex in both liquid form and capsules.

Samples and literature will be available.

50. American Hospital Supply Corporation, Chicago.

You have heard about Baxter Transfuso-Vacs and Plasma Vacs, which are revolutionizing blood transfusions and blood banking. See them demonstrated in the booth of the American Hospital Supply Corporation.

Among the many other notable specialties on display will be the Tomac Gastro-Evacuator, Junior Oxygenaire, Insufflator and Face Mask, Coli-Bactragen, Sur Masks and so forth. Spend fifteen minutes in the booth to examine these products.

51. Standard X Ray Sales Corporation, Boston.

The Standard X Ray Sales Corporation has good news for the medical profession and cordially invites you to its booth to inspect the remarkable new shock proof ultra full-length fluoroscopic table. This table has been recently developed by the Standard X Ray Company of Chicago, Illinois which is a pioneer in the manufacture of x ray equipment. Incorporated in this table are all desirable features, many of which are not found in other tables. It is entirely new in principle, convenient, and most dependable. It is the table that you have always wanted but could not buy. With this will be shown other equipment of the latest shockproof design.

52. Sandoz Chemical Works, Incorporated, New York City

Physicians will be interested in Gynergen (ergot amine tartrate) for migraine therapy. Newer pharmaceuticals also displayed include: Digiloid, chemically pure, crystallized initial glycosides of *Digitalis lanata*; Calcibronat, a synergistic combination of calcium and bromine; Basergen, a stable preparation of crystalline ergonovine tartrate; Neo-Gynergen, a well-balanced combination of ergotamine and ergonovine for obstetric and gynecological use. Other well-known Sandoz preparations are: Calglucon and Neo-Calglucon, Bellafoline, Belladenal, Bellergal, Scillaren and Quinine Calcium-Sandoz.

53. Abbott Laboratories, North Chicago, Illinois.

You are heartily invited to visit this exhibit of Council-accepted preparations. The Abbott-trained representatives in attendance will be glad to discuss the newer products with you.

Be sure to drop in and register!

54. Sharp and Dohme, Incorporated, Philadelphia.

The new modern display of Sharp and Dohme will feature Propadrine Hydrochloride products, Lyovac Bee Venom Solution and other Lyovac biologicals. There will also be on display a group of new pharmaceutical specialties and biologicals prepared by this house, such as Rabellon, Daldin, Padrophyl, Elixir Propadrine Hydrochloride, Riona Depropanex and Ribothron. Capable, well-informed representatives

- will be on hand to welcome physicians and furnish information on Sharp and Dohme products
- 55 Nestle's Milk Products, Incorporated, New York City
Nestle's Milk Products, Incorporated, makers of milk products and infant dietary materials for more than fifty years, will feature Lactogen in their exhibit. Physicians interested in infant feeding are cordially invited to visit the Nestle booth.
- 56 Cambridge Instrument Company, Incorporated
Cambridge Instrument Company, Incorporated, pioneer manufacturers of the electrocardiograph, is showing its Hindle electrocardiographs and stethographs. Particular attention is given to the Simpli-Trol portable electrocardiograph and stethograph, the precision instrument which weighs only 33 pounds. The exhibit will be chiefly of interest to heart specialists.
- 57-58 Pet Milk Company, St. Louis, Missouri
An actual working model of a milk-condensing plant in miniature will be exhibited by the Pet Milk Company. This exhibit offers an opportunity to obtain information about the production of Irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the Pet Milk booth.
- 59 Kellogg Company, Battle Creek, Michigan.
The Kellogg Company is exhibiting various ready-to-eat cereals. Pep 30 Per Cent Bran Flakes are now fortified with vitamins B₁ and D. An interesting display of foods containing vitamin B₁ will be displayed. Complete information concerning the manufacture and food value of all Kellogg cereals is available, together with vitamin and calorie charts.
- 60 The Coca-Cola Company, Atlanta, Georgia.
Coca-Cola will be served with the compliments of The Coca Cola Company.
- 61 Chr. Hansen's Laboratory, Incorporated, Little Falls, New York.
This is The Junket Folks' booth, with a graduate dietitian in attendance. Free servings of rennet-custards made with Junket Rennet Powder and Junket Rennet Tablets will be furnished. Authoritative literature describes the action of the rennet enzyme on milk and the place of rennet-custards in the diets of convalescents, postoperative patients, invalids, infants, children and so forth. There will be a display of Junket Brand food products.
- 62 Cameron Surgical Specialty Company, Chicago
See the new Cameron Color-Flash Clinical Camera, the Projectoray and the latest Cameron Lempert Headlite demonstrated in the booth of the Cameron Surgical Specialty Company. Latest developments in electrically lighted diagnostic and operating instruments for all parts of the body will be shown. Of special interest will be the new inexpensive office model Radio Knife and other electrosurgical units for cutting, coagulating, desiccating and fulgurating in all sizes from the office model up to the hospital unit with sufficient power for major surgery and transurethral prostatic resections.
- 63 Lee DeForest Laboratories, Boston.
Lee DeForest Laboratories are exhibiting short-wave apparatus available for electrosurgery, hyperpyrexia and all general therapy work. In the same booth will be demonstrated Marvel Portex shockproof x-ray apparatus.
- 64 H. J. Heinz Company, Pittsburgh.
Physicians interested in prescribing for feeding problems—especially in infants, older children or adults requiring soft diets—will be interested in the new Heinz exhibit where Strained and Junior Foods are attractively displayed. Mr. A. J. McGarry is in attendance and will be happy to supply information on these foods.
The eighth edition of the popular Heinz Nutritional Charts, containing greatly expanded charts and new data on the vitamin content of foods, is ready and will be mailed on request.
- 72 Massachusetts State Pharmaceutical Association, Incorporated, Boston.
The Massachusetts State Pharmaceutical Association, Incorporated, will show a model prescription working bench, which has been loaned to it through the courtesy of the Massachusetts College of Pharmacy. It will also display several little known U.S.P. and N.F. pharmaceutical preparations attractively packaged.

LADIES' PROGRAM

A very interesting program for the ladies of the members' families has been arranged for this year by the Ladies' Committee, consisting of Mrs. Walter G. Phippen, chairman, Mrs. J. Frank Donaldson, Mrs. Thomas H. Lanman, Mrs. Roger I. Lee, Mrs. Charles C. Lund, Mrs. F. W. Marlow, Jr., Mrs. Donald Munro, Mrs. Edward L. Pearson and Mrs. W. B. Robbins.

The ladies' registration desk will be in the main lobby of the Copley-Plaza.

TUESDAY, MAY 21

Registration, Copley-Plaza Hotel. Drive to Gore Place, Main Street, Waltham (admission 25c) and to Mrs. Arthur Lyman's garden, Lyman Street, Waltham, buses leave Copley-Plaza Hotel at 2:00 p.m.

Dinner at Horticultural Hall at 7 p.m. to meet Mrs. Phippen and the wives of the district presidents (dinner \$1.50). Buses leave Copley-Plaza Hotel at 6:30 p.m. Dress optional.

"Pop" Concert at Symphony Hall at 8:30 p.m. (tickets \$1.00). The "Pop" Concerts are given by members of the Boston Symphony Orchestra. Messrs. Frey and Braggiotti will play.

WEDNESDAY, MAY 22

Registration. Trip to Salem from 9:30 a.m. to 3:00 p.m. Buses leave Copley-Plaza Hotel at 9:30 a.m. Peabody Museum, Essex Institute, Pingree House and a Salem garden will be visited before luncheon at the Salem Country Club at 1:30 p.m. (luncheon \$1.00). There will be no charge for transportation either day.

Those ladies who wish may play golf on Wednesday afternoon at the Salem Country Club. The greens fee will be \$1.75, and Mrs. Edward L. Pearson will be at the

job to help those who wish to play. All ladies who remain in Salem to play golf must provide their own transportation home, as the buses carrying the ladies party will return to Boston soon after luncheon.

ANNUAL GOLF TOURNAMENT

The annual golf tournament of the Massachusetts Medical Society will be held at the Belmont Country Club on the afternoon of Tuesday May 21.

The Burrage Bowl, emblematic of the Society championship, will again be in competition. The two names already engraved on this trophy are those of Dr. Roy E. Mahrey (1938) and Dr. H. H. Serunian (1939). Numerous other prizes will be offered for both net and gross scores.

Play will commence at 1:00 p.m. and the greens fee for eighteen holes will be \$2.00. If two or more rounds are played during the afternoon the fee will be \$2.50. State handicaps will be used.

Luncheon may be had at the club at 75 cents, and all the privileges of the club will be open to the members of the Society who enter the tournament. Dr. W. T. Halloran, of the Committee of Arrangements has direct charge of the tournament.

MASSACHUSETTS MEDICO-LEGAL SOCIETY

There will be a meeting of the Massachusetts Medical Society in the State Dining Room at the Copley Plaza Hotel on Tuesday afternoon May 21, at 2:30.

TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

There will be a luncheon of the Tufts College Medical School Alumni Association at the time of the Massachusetts Medical Society's Annual Meeting on Tuesday May 21 at 12:30 p.m. All alumni and friends are invited to attend.

MISCELLANY

ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to Herbert R. Glodt 41 for his paper "The Diabetic as a Surgical Problem" which will appear in the forthcoming issue of the *Tufts Medical Journal*.

NOTE

The annual meeting of the New England Society of Psychiatry was held at the Danvers State Hospital Thursday April 25. Dr. Roy D. Halloran, superintendent of the Metropolitan State Hospital Waltham, Massachusetts, was elected president for the ensuing year. Other officers elected at that meeting were as follows: vice-president, Dr. George E. McPherson, superintendent of the Belcher town State School, Belchertown, Massachusetts; secretary-treasurer, Dr. Bardwell H. Flower, counselors, Dr. Charles H. Dolloff, New Hampshire State Hospital Concord, New Hampshire, and Dr. George A. Elliott, Connecticut State Hospital Middletown, Connecticut. At this meeting the society learned with sorrow of the death of its oldest living past president, Dr. G. Alder Blumer of Providence, Rhode Island.

CORRESPONDENCE

CONNECTICUT COUNTY HEALTH OFFICERS

To the Editor: I just read the editorial on page 601 of the April 4 issue of the *Journal* on turning over to page 602, the first sentence reads as follows: "This committee did however uncover a law in Connecticut that requires that county health officers be lawyers!" I presume the report itself went into detail in regard to the duties of the Connecticut county health officer when that law existed. The Connecticut County Health Officer Law was repealed in 1939 and the duties of the county health officer have been taken over by the local prosecutor, the town board of selectmen and the State Department of Health.

Your editorial gave readers the idea that the county health officer of Connecticut, a lawyer was doing general public-health work. Such was not the case. May I refer you to copies of Section 2402 and Section 2403 of the 1930 General Statutes of Connecticut, which as I mentioned above, were repealed in 1939. The statutes, when the law existed, provided that the county health officer should cause the execution of laws relating to public health nuisances, dangers to public health, and vital statistics and should co-operate with and supervise the activities of town, city and borough health officers and boards of health within each county. The county health officer had all the powers of a grand juror and all the powers of a prosecuting officer of each city, borough, town or police court for violations of public-health and vital statistics laws and for violation of by-laws or ordinances relating to public health, contagious diseases, the practice of medicine and midwifery, the sale of poisons and the sanitary code. The county health officer appointed town health officers and approved their bills, which, once approved, the town paid. Thus, the county health officer supervised the doings of the town, city and borough health officers who the statute directed should be some discreet person learned in medicine and sanitary science.

The county health officer was first authorized in 1893 and continued until June 30, 1939 and did much to enforce the health officers' orders, rules, regulations and doings in the towns and cities of Connecticut.

STANLEY H. OSBORN, Commissioner

State of Connecticut Department of Health
Hartford, Connecticut

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

To the Editor: In addition to the articles enumerated in our letter of March 2 the following have been accepted:

The Drug Products Company

Hyposols Dextrose 10 gm. (buffered) 20 cc.
Hyposols Dextrose 25 gm. (buffered) 50 cc.

Mallinckrodt Chemical Works

Urea Pure Crystals—Mallinckrodt

Maltbie Chemical Company

Ampules Sodium Cacodylate—Maltbie 0.1 gm.
(1½ gr.) 1 cc.
Ampules Sodium Cacodylate—Maltbie 0.2 gm.
(3 gr.) 1 cc.
Ampules Sodium Cacodylate—Maltbie 0.25 gm.
(5 gr.) 1 cc.

Ampules Sodium Cacodylate—Maltbie 0.5 gm (7½ gr), 5 cc.

Ampules Sodium Cacodylate—Maltbie 1.0 gm (15½ gr), 5 cc.

Merck and Company, Inc.

Sulfapyridine Sodium Monohydrate—Merck

Parke, Davis and Company

Kap seals Theclol, 0.24 mg

Sandoz Chemical Works, Inc.

Digilanid

Tablets Digilanid, 0.33 mg (1 cat unit)

Digilanid Liquid, 0.33 mg per cc (1 cat unit)

E. R. Squibb and Sons

Sulfapyridine—Squibb

Capsules Sulfapyridine—Squibb 0.25 gm (3¾ gr)

Tablets Sulfapyridine—Squibb 0.5 gm (7½ gr)

The Upjohn Company

Ampules Bismuth Subsalicylate with Chlorobutanol in Oil, 1 cc.

Bismuth Subsalicylate with Chlorobutanol in Oil, 30 cc. vials

Frederick Stearns and Company

Stearns Cod Liver Oil

Winthrop Chemical Company, Inc.

Ampules Pontocaine Hydrochloride "Niphanoid," for spinal anesthesia, 10 mg

Ampules Pontocaine Hydrochloride "Niphanoid," for spinal anesthesia, 20 mg

The following product has been accepted for inclusion in the list of articles and brands accepted by the Council but not described in N.N.R. (*New and Nonofficial Remedies*, 1939, p 528)

Num Specialty Company

535 North Dearborn Street,
Chicago, Illinois

REPORTS OF MEETINGS

BOSTON CITY HOSPITAL

At the Boston City Hospital on January 29, Dr Otto J Hermann introduced Dr Roger Anderson of Seattle, Washington, who spoke on "Delayed Union and Non-Union Ninety per cent preventable." In elucidating the statement that proper reduction and immobilization are the fundamental prerequisites for this prevention, the speaker emphasized that in regard to immobilization this means sustained apposition of the fragments throughout convalescence as well as during the early course of healing. He stated that traction, whether skin, bone or Russell, really varies considerably with the changes in countertraction entailed in the change of position of the patient for such necessary maneuvers as feeding and defecation. Dr Anderson contended that such allegedly inconsequential and temporary movements of the fragments contribute to delay if not prevention of union in fractures.

Additional factors in faulty immobilization enumerated include plaster or celluloid spicas for femoral and hu-

meral fractures. With the former, motion is allowed by the necessary arrangements for the toilet, while the latter must permit room for respiration. Dr Anderson also cited tapering casts for the lower leg and hanging cast for the humerus as examples of poor external method of maintaining proper apposition of broken bones. Fixation by open operation is seldom indicated because of in addition to already existing vascular trauma and for its possible inefficiency in many cases. An unusual type of distraction is that caused by an intact fibula in the presence of a fractured tibia. Dr Anderson suggested its treatment by making an oblique fracture of the fibula and overcorrecting the tendency for a varus deformity. Potentially the worst form of distraction, it was stated, is that brought about by the double pin in the presence of absorption of the ends of the bone fragments.

Among causes of faulty reduction Dr Anderson included "continuous" traction, needless operative interference, failure to achieve proper apposition consequent to incomplete roentgenograms, and later absorption at the ends of the fragments with subsequent distraction.

Recommendations advanced by the speaker were based on his theory of controlling the proximal fragment of fractured shafts of long bones rather than attempting to devise bizarre positions for bringing the peripheral fragment into line. His fundamental principle is the use of intimate skeletal transfixion for countertraction. This was referred to as a functional method of immobilization. Reduction may be accomplished by any established method but should be checked both by fluoroscope and roentgenograms in various planes before plaster is applied. Two half pins, which have been originally placed at about a 45° angle to each other at the end of each fragment, are then incorporated in plaster or a special bar. The obliquity of the pins prevents lateral motion.

Regarding the technic of inserting the pins, Dr Anderson stated that it is wiser to use long rather than short ones in order to ensure their protrusion through the opposite side of the shaft. He expressed the belief that timidity on the part of the operator has no foundation in fact and that failure to traverse the bone is one cause of faulty immobilization by this method. Another suggestion offered was that the pins should always be placed as near the joints as possible, so that they will be in vascular bone rather than the gas-pipe shaft.

Dr Anderson has used this method of fixation in all types of fractures of the shafts of long bones, including those near the joints and pathologic fractures. Contrary to the usual concept that both the joint above and below the fracture site should be immobilized, Dr Anderson's method allows practically unlimited motion of surrounding joints. Plaster casts extend only to the adjacent joint, and the patients are encouraged to exercise the uninvolved parts of a limb freely. This was believed to be beneficial not only in preventing troublesome ankylosis but also in promoting the circulation to the fractured bone. The possibility of having patients ambulatory also increases their appetite and improves all bodily function, while their ability to return home relieves an economic burden and allows them to assume a more normal existence.

One of the most important features of the method is the gradual diminution of the distance between the opposite pins, which keeps the fragments in apposition. Dr Anderson is certain that absorption is fairly common and that even in its absence by x ray such a procedure is advisable. This is accomplished by removing a circular strip of cast and then reapplying plaster in the new position. When the Anderson bar is used, the same end may be gained by adjustable screws.

Dr Anderson cited the usefulness of such a method during the exigencies of war when time, men and hospital beds are at a premium. Indeed it was suggested that even in civilian practice only one man need scrub. The bar would be particularly useful in war injuries complicated by sepsis, for arrangements can be easily made for dressings, and bars can be shaped for any type of wound or dressing.

In conclusion Dr Anderson stated that the increase of non-union at the expense of mal-union is a result of the new era of surgical and traction methods of treating fractures. In summing up the advantages of his method of controlling the upper segment he stated that it had not only those mentioned in regard to the doctor and patient but also the additional merit of decreasing the interest in socialized medicine as a result of the decreased hospitalization and loss of work. He emphasized, however, that the method demands accurate knowledge of the apparatus, which improperly managed is probably the most potent source of distraction yet devised.

The discussion, which followed the showing of motion pictures depicting the early return to function in Dr Anderson's cases, was inaugurated by Dr Buckley of Brockton who demonstrated several patients successfully treated by this method. Dr Buckley and later Dr Sever reiterated Dr Anderson's warning of the dangers entailed in the procedure when used by uninformed or inexperienced operators.

Dr Anderson was then asked to answer several questions. He said that he regards sepsis as only a rare complication usually occurring in mishandled cases later referred to the clinic. The danger of interposition of soft tissue is avoided by unlocking all such predisposing fractures by rotation before reduction is performed. The chances of infection were found to be proportional to the number of assistants to the distance of the pins from the vascular bone toward the shaft, and to the failure of the pins completely to traverse the bone due to their shortness. It was stated, however that drainage may persist, particularly in the dense poorly vascularized portion of the bone, as a result of aseptic irritation. Removal of the sequestrum quickly ends the discharge, if it does not do so spontaneously. In wounds complicated by gas-bacillus infection, one waits until the infection has subsided before instituting treatment of the fracture by the Anderson method. But in compound fractures fixation is carried out immediately. The system has been found satisfactory in the management of pathologic fractures, including those occurring in Paget's disease.

Dr Anderson reminded his audience that aftercare is as important with this type of treatment as elsewhere. Fractured femurs should be protected for three to six months, for instance, but many patients can carry on their jobs capably during this time.

Dr Shortell lauded the surprising amount of motion of the adjacent joints secured by Dr Anderson's method but questioned on the basis of local statistics, the high incidence of non-union cited. Dr Anderson, in reply pointed out that his aim was not solely to prevent non-union but also to decrease the amount of delayed union, which is an important consideration, particularly for laboring people.

Marie, was that of a thirteen-year-old girl who complained of hemoptysis and pain in the right chest for three weeks. Physical examination revealed signs consistent with atelectasis of the right upper lobe and this was confirmed by roentgenograms. Bronchoscopy was carried out and demonstrated a smooth 6-mm. mass in the right upper-lobe bronchus, which was diagnosed pathologically as fibrosarcoma. The second case was presented by Dr Magnus I Smedal, of Boston. A sixty-two-year-old man first had a chief complaint of abdominal distress, occasional vomiting and some dysphagia. For thirty years he had had "dyspepsia" and five years prior to admission he had been placed on a Sippy regimen following a bout of pain and hematemesis. Three months before admission an x-ray diagnosis of obstructing duodenal ulcer and gallstones was made, and large areas of calcification were noted in the lower abdominal cavity. An operation was performed for removal of the stones and the freeing of adhesions, but all the symptoms returned within a few days. Seven months later a gastrointestinal series revealed a questionable postoperative defect in the duodenum and the same areas of calcification were noted in the lower abdomen. At operation 210 cm. of ileum was removed for chronic inflammation the areas of calcification proved to be large laminated gallstones within the ileum. The case was considered an example of chronic intestinal obstruction due to liberation of stones into the gastrointestinal tract following rupture of the gallbladder five years before. The final case, presented by Dr Leslie K. Sycamore, of Hanover New Hampshire, was that of a twenty-six year-old horseman who entered the hospital unconscious and cyanotic following an accident. He regained consciousness in three days, but pain in the chest persisted for two weeks. There were occasional hemoptyses and persistent cough and dyspnea but the patient left the hospital against advice in one month. Pain recurred after two weeks, and there was increasing dyspnea until readmission after three months. Roentgenograms revealed atelectasis of the left lung which Lipiodol demonstrated to be due to obstruction of the left main bronchus. A provisional diagnosis of fractured bronchus was made and was confirmed by bronchoscopy. Treatment with pneumothorax afforded the patient some relief. Dr Sycamore stated that although such injuries are usually caused by crushing accidents and are fatal they occasionally have been reported without signs of external fractures. There have been only 6 reported recoveries.

The first paper of the evening was by Dr William J Elliott, of Worcester on "The Non-Medical Use of Roentgen Rays." The speaker cited several practical industrial roles of the roentgen ray. The presence of gas inclusions and internal stress were readily demonstrated in metals, and knowledge of diffraction patterns has been useful in chemical analysis. Fluoroscopy is valuable to large food concerns in the detection of opaque foreign bodies in packages and canned goods. One of the most useful roles of the roentgen ray is in the detection of fraudulent art works, Dr Elliott stated. Infra red rays are an indispensable adjunct in determining minor surface repairs while roentgen rays reveal the characteristic brush stroke so clearly as to allow spurious paintings to be detected and the true source of anonymous works to be discovered.

The final paper of the evening was delivered by Dr Francis T Hunter of Boston, on "Archaeology and Roentgenology." Interesting slides depicted how science in the form of roentgen rays had allowed archaeologists to compare the efficacy of various methods of preparing mummies. The determination of the state of preservation of the body as well as the detection of unusual inclusions within the mummy case, aided the research materially.

NEW ENGLAND ROENTGEN RAY SOCIETY

A regular meeting of the New England Roentgen Ray Society was held at the Boston Medical Library on February 16 with Dr Langdon T. Thaxter presiding.

There were three short case presentations. The first case, presented by Dr Roland D. Clapp of Lewiston

NOTICES

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, May 15, from 2 to 4 p.m. Drs. John Homans and E. A. Stead will speak on "Edema."

Physicians and students are cordially invited to attend

BOSTON ORTHOPEDIC CLUB

There will be a meeting of the Boston Orthopedic Club at John Ware Hall of the Boston Medical Library on Monday, May 13, at 8 00 p.m. Dr. Henry Graham will present a paper on "An Efficient Method for the Reduction and Immobilization of Colles' Fractures"

BOYLSTON MEDICAL SOCIETY

There will be a meeting of the Boylston Medical Society in Amphitheater C of the Harvard Medical School on Monday, May 13, at 5 00 p.m. Professor C. H. Best, of the University of Toronto, will speak on "Factors Influencing the Production and Liberation of Insulin from the Pancreas"

NEW ENGLAND PEDIATRIC SOCIETY

The next meeting of the New England Pediatric Society will take place on Wednesday, May 15. The clinical presentation will be held at the Massachusetts General Hospital, and all the other events at Longwood Towers, Brookline.

PROGRAM

- 4 00 Clinical presentation by staff at Massachusetts General Hospital.
- 6 15 Refreshments
- 7 00 Dinner
- 8 15 Symposium on Adolescence.

Psychological Disturbances and Adjustments of Adolescence. Dr. James S. Plant, Newark, New Jersey

Scholastic Difficulties of Adolescence. Mr. C. E. Allen.

Disturbances of Menstruation and Ovulation of Adolescence. Dr. John Rock.

Physicians are cordially invited to attend the clinical meeting and the symposium.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The annual meeting of the New England Society of Physical Medicine will be held on Wednesday evening, May 15, at the Ring Sanatorium and Hospital, 163 Hillside Avenue, Arlington Heights, Massachusetts.

The council will meet at 6 00, and dinner will be held in the main dining room of the sanatorium at 6 30. At 8 00 Dr. Robert S. Harris will speak on the subject, "Some Nutritional Researches." Dr. Francis L. Burnett will open the discussion.

All members of the medical profession are cordially invited to attend the scientific program

AMERICAN MEDICAL GOLFING ASSOCIATION

The American Medical Golfing Association's twenty-sixth annual tournament will be held at the Winged Foot Golf Club, Mamaroneck, New York, Monday, June 10

Winged Foot has two famous championship courses and a beautiful clubhouse

Some 250, out of the 1360 members of the association, are expected to take part in the thirty-six hole competition. Each contestant will play both courses. The hours for teeing off are from 7 00 a.m. to 2 00 p.m. The sixty prizes in the nine events will be distributed after the banquet at the clubhouse at 7 00 p.m.

All male members of the American Medical Association are eligible and cordially invited to become members of the association, and applications should be obtained from the executive secretary, Bill Burns, 2020 Olds Tower, Lansing, Michigan. Each participant in the tournament is required to present a card with his home-club handicap, signed by the club secretary, at the first tee on the day of play, no handicap over 30 is allowed. Only active members of the association may compete for prizes. No trophy is awarded to a member who is absent from the annual dinner, which is always worth while waiting for!

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MAY 12

MONDAY MAY 13

5 p.m. Factors Influencing the Production and Liberation of Insulin from the Pancreas. Professor C. H. Best. Boylston Medical Society Amphitheater C Harvard Medical School

8 p.m. An Efficient Method for the Reduction and Immobilization of Colles Fractures. Dr. Henry Graham. Boston Orthopedic Club. Boston Medical Library, 8 Fenway, Boston

TUESDAY, MAY 14

*9-10 a.m. Studies in Urobilinogen Metabolism. Drs. Karl Singer and Edward B. Miller. Joseph H. Pratt Diagnostic Hospital.

*12 m. Emergencies in Medical Practice. Dr. William B. Brind. South End Medical Club. Boston Tuberculosis Association, 534 Columbus Avenue, Boston

*8 15 p.m. Important Factors in Development as Revealed by Early Stages of the Macaque Embryo. Dr. George L. Streeter. Journal Club. Boston Lylog in Hospital

WEDNESDAY MAY 15

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*2-4 p.m. Edema. Drs. John Homans and E. A. Stead. Peter Bent Brigham Hospital

*4 and 8 15 p.m. New England Pediatric Society. Massachusetts General Hospital and Longwood Towers, Brookline.

THURSDAY MAY 16

*9-10 a.m. Huntington's Chorea. Dr. A. Warren Stearns. Joseph H. Pratt Diagnostic Hospital

FRIDAY MAY 17

*9-10 a.m. Obesity. Dr. Mark Falcon Lesser. Joseph H. Pratt Diagnostic Hospital

SATURDAY MAY 18

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital

*Open to the medical profession

BOOK REVIEWS

Minor Mental Maladjustments in Normal People Based on original autobiographies of personality maladjustments J. E. Wallace Wallin. 298 pp. Durham North Carolina. Duke University Press, 1939 \$3.00.

This book, based upon autobiographical material obtained from about three hundred of the author's graduate and undergraduate students, is intended for use as source or case book for students of "mental hygiene psychology education, child development, sociology and the formation of personality traits." As might be expected in view of their source the case histories are superficial, objective and largely descriptive at a contemporary level. Taken for what it is, however the material does illustrate a wide range of minor clinical symptoms in normal people—fears, phobias, dreads, anxieties, worries, obsessions, compulsions, dreams, nightmares and feelings of inferiority and inadequacy to name only a few of the topics dealt with. The author in organizing the material has broken up the case histories, using one part to illustrate one set of symptoms in one chapter and another part of the same history to illustrate a different set of symptoms in another chapter. As a result, nowhere in the book does a complete individual biography emerge as an integrated whole. One could scarcely plan a more convincing demonstration than this book provides of the sterility of academic psychology when faced with clinical phenomena judging from his book, the author would seem to have very little familiarity with the teachings of Adolf Meyer and the body of medical knowledge called psychobiology.

Otolaryngology in General Practice Lyman G Richards. 352 pp. New York The Macmillan Co. 1939 \$6.00.

Starting with the premise that in recent years no book has been written especially for the general practitioner, who, either by election or through force of circumstance, has ear nose and throat problems to solve, Dr Richards has contributed a clearly written, neatly arranged and excellently illustrated book that should adequately supply his need.

Each chapter heading, with few exceptions, is a major symptom from which a patient may be seeking relief, and under the symptom are discussed the various possible

pathologic conditions that might cause it, with a description of and proper therapeutic measures for each.

The operative procedures advocated are of the simplest type and clearly described, and are those which experience has demonstrated to be safe and adequate.

Several approved techniques for removal of the tonsils and adenoids are illustrated and due consideration is given to the aftercare and possible complications that sometimes arise during the postoperative period.

The chapter on respiratory obstruction is especially well done and could be read with profit by anyone in the practice of medicine, surgery or pediatrics.

Considering the fact that this book was written by one man, there are surprisingly few statements to which one could take exception and these in no way interfere with its main purpose. Although written specifically for the general practitioner the book should be of value to the student and of interest to the otolaryngologist.

Circulatory Diseases of the Extremities John Homans. 330 pp. New York The Macmillan Co., 1939 \$4.50

The present generation of physicians and laymen has become impatient with chronic disorders, whether they occur in the young or in those who are middle-aged. This has resulted in an enormous amount of work on the diseases of the peripheral circulation and within the past few years a large number of books have appeared on these disorders. Unfortunately these monographs, for the most part, have confined themselves to diseases of either the veins or the arteries and moreover they have usually been dedicated to the espousal of some particular form of therapy.

Dr Homans's book is the first in a long while to attempt a comprehensive survey of the diseases of the arteries, veins and lymphatics of the extremities and it is refreshingly unique in its avoidance of therapeutic prejudice.

The author is well qualified to handle his subject, having a background of many years of fruitful work in this field. He is widely known for his original observations, especially in the realm of the veins and lymphatics. His long experience as a teacher is reflected in the intimate, conversational tone of the book, which makes for particularly pleasant reading. There are innumerable references to cases seen, and even when these are set off as reports, they are interspersed with a running comment on the significance of the points raised. He is not averse to questioning the wisdom of the treatment used in any individual case, and he suggests alternatives that might have been tried in just such a case.

The book opens with a chapter on "Sorting Out the Vascular Disorders of the Limbs, which outlines the normal physiology of the peripheral circulation and includes details of the diagnostic methods used. Arteriosclerosis, thromboangiitis obliterans, arterial embolism and spastic diseases of the arteries are then individually considered. In the treatment of each disease, Dr Homans discusses the hygiene of the limbs, in addition to the medical physiotherapeutic and surgical methods. The important diagnostic and therapeutic procedures are illustrated by clear drawings, and references are given to important sources. An attitude of rational conservatism is quite evident.

In the chapter on varicose veins, emphasis is given to the physiologically conceived division of the veins at strategic points, and the injection of sclerosing solutions is characterized as an aid to this process. Considerable space is devoted to pulmonary embolism as a complication of thrombophlebitis. It is suggested that veins showing a

minimum of reaction are usually the source of such emboli. The author suggests that the large venous trunks be ligated in order to prevent this accident. Postphlebotic ulcerations are treated as peculiarly specific entities. Many disagree with this attitude and contend that the therapeutic results justify the classification of these lesions as varicose ulcers of particular severity.

A concise account of peripheral aneurysms and arteriovenous communications then follows. Finally, the author adds a section on the lymphatic system. His previously reported observations on lymphedema are again presented. He has obtained excellent results in long-standing cases by an excision of the subcutaneous fat and the deep fascia, a modification, in fact, of the Kondoleon operation. Dr. Homans explains the excellent results of this procedure not by the formation of new lymphatic pathways, but rather by the removal of lymph-bearing tissue.

If one is disappointed in not finding an exhaustive treatment of each subject, it should be emphasized that our knowledge of these disorders is in a state of flux. The author has intended to present readily available information for the practitioner and student, and to make the volume one "which will not be quite out of date in five years." This promise seems well fulfilled, and the volume should be owned by all interested in the subject.

Electrocardiographic Patterns Their diagnostic and clinical significance Arlie R. Barnes 197 pp. Springfield, Illinois, and Baltimore Charles C. Thomas, 1939 \$5.00

This book is an important milestone in the history of electrocardiography. As the author points out in the introduction, the electrocardiograph has outgrown its original importance as an instrument in the analysis of cardiac arrhythmias. Its chief value now lies in the information which it is able to give about the unbalanced electrical effects within the heart dependent on alterations of myocardial structure and preponderant effect of unilateral cardiac strain. The author and his associate, Whitten, were pioneers in pointing out these newer concepts and investigating the possibilities of the localization of cardiac infarcts by means of the electrocardiograph.

The first three chapters discuss the anatomy of the coronary arteries and their relation to acute myocardial infarction, and the electrocardiographic findings during the acute and healing stages of cardiac infarction. The next three chapters are concerned with the electrocardiogram in ventricular strain of left or right type. A detailed chapter follows on the changes due to pericarditis, and then one on the effects of certain drugs, metabolic disorders and infections. The final chapter contains observations relative to precordial leads. The literature is covered in all its essential particulars. The illustrations are excellent, and the correlation of the electrocardiographic findings with the autopsy data gives very important information. The method for illustrating the changes in the different leads is very convenient, as the tracings are superimposed on light-shaded diagrams of the normal findings in the same leads.

The text will repay extensive study, and the book serves as a valuable reference in the analysis of difficult electrocardiographic problems. There is one unfortunate situation which the author recognizes, that is, the descriptions and illustrations of the chest lead are those which were used before the Committee for the Standardization of Precordial Leads determined what would be the acceptable formula. As a result, these leads have the reversed polarity to those now in common use, and the reader is forced to make a mental reversal of all the waves and of

their description in the text before they conform to the present practice. This is somewhat confusing even to those who are fairly conversant with electrocardiographic interpretations. In spite of this, it is to be expected that this book will receive the wide distribution which it deserves among serious students of electrocardiography. The approach by electrocardiographic patterns characteristic of certain diseases is a highly practical method and is particularly adaptable to the correlation between electrocardiography and clinical medicine.

The Art of Anaesthesia Paluel J. Flagg Sixth edition, revised 491 pp. Philadelphia, London, and Montreal J. B. Lippincott Co., 1939 \$6.00

This book is a most excellent treatise on inhalation anesthesia, but is rather more limited in its scope than seems implied by the broad term "anesthesia." Concerning inhalation anesthesia the author speaks with authority from his wide and extended experience. Particularly is this true when intratracheal anesthesia is discussed. His position throughout is sound and highly conservative, as he advocates chiefly such well-tried agents as ether, and nitrous oxide and oxygen. It is a distinct loss, however, that such important and widely used methods as spinal anesthesia and intravenous anesthesia are not presented with the same clear and sound discussion. Various minor criticisms could be made, for example, the classification of the signs of anesthesia is somewhat different from that employed by most anesthetists today, and in particular, the conception of an ascending paralysis in deep ether anesthesia seems misleading in that it is distinctly different from the view generally accepted.

While the book covers the field of inhalation anesthesia rather than that of anesthesia, too much praise cannot be given the presentation of what is covered. The pages are packed full with sound advice.

Sterility and Impaired Fertility Pathogenesis, diagnosis and treatment Cedric Lane Roberts, Albert Sharman, Kenneth Walker, and B. P. Wiesner 419 pp. New York Paul B. Hoeber, Inc., 1939 \$5.50

This is an excellent book on the diagnosis and treatment of sterility. The first half is devoted to the male factor in childless marriages, and is a very careful and thorough presentation of the subject. Various chapters take up the constitution of the semen, the assay of male fertility and disturbances in the reproductive mechanism and their treatment, including the endocrine factors.

A similar detailed study is presented of the problem as it appears in women, and here too there is a description of the endocrine balance which is as complete as present-day knowledge allows.

There is an appendix giving laboratory techniques for the examination of semen, the determination of hormones in the urine, the preparation of vaginal smears and so forth. There are a large number of excellent illustrations, and an adequate index.

One might say that the book is somewhat too detailed for the man who is only casually interested in sterility. For those physicians who do considerable work in this field, however, it is a very complete summary of knowledge to date and the price puts it within reach of every body. There are, of course, minor statements with which the reviewer disagrees, but they in no way detract from the general excellence of the book.

FRACTURES OF THE CARPAL SCAPHOID*

AUGUSTUS THORNDIKE JR. M.D.,† AND WALTER E. GARREY M.D.‡

BOSTON

AMONG the more commonly undiagnosed fractures in our experience are those of the carpal scaphoid (os naviculare). During the last five years 17 cases have been observed by one of us (A.T.) in a college clinic. Particularly is it oote

Colles fracture. At Boulder Dam, drawing from a wider and mostly older age group, Jackle and Clark³ observed 17 such fractures, as compared to 63 fractures of the radius. On the other hand, in a group of men similar in age to our patients

A

B

FIGURE 1 Case C S

Film A taken elsewhere at the time of injury is negative. Film B, taken six months after the injury which had been unreported and untreated, shows a fracture through the proximal third of the carpal scaphoid.

worthy that 11 (65 per cent) were old or previously unrecognized fractures.

The incidence of these fractures is especially high among young men active in sports in which violent hyperextension of the hand takes place. This has long been recognized and has caused the fracture to be called in France *fracture du gymnaste*.¹ Our cases have all occurred in young men between the ages of sixteen and twenty five, and the incidence has been four times that of

but engaged in more extensive gymnastic work. Hopkins⁴ observed 23 cases in twelve years, as against 2 Colles fractures. It thus seems evident that the trauma which in children produces a separation of the radial epiphysis and in adults causes Colles fractures may in the very young adult produce a fractured carpal scaphoid.

The diagnosis of these fractures, under a definite method of clinical and roentgenological examination, should not be overlooked. The standard signs are limitation of motion in extension and radial deviation, and tenderness over the anatomical snuffbox and on the palmar surface over the tubercle of the bone. However, there are oumer-

ous diagnostic pitfalls, the obvious one being the incorrect diagnosis of sprained wrist. Eleven of our patients failed to receive prompt treatment because their injury had originally been inter-

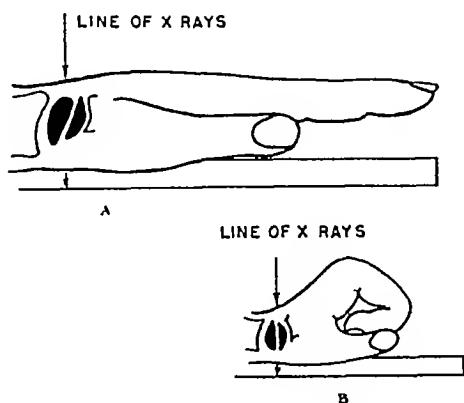

FIGURE 2 *The Optimum Position for Demonstrating by X-Ray a Fracture of the Carpal Scaphoid (Reproduced from American Journal of Surgery [44:101, 1939] by courtesy of the publisher)*

preted as a mild sprain. In 2 cases the youths consulted no one. The initial discomfort was so mild that they did not report their injury, although they were examined daily and not until five

demonstrated in the initial x-ray plates has been mentioned in almost every recent article³⁻⁶ on the subject. In some cases it seems that the central beam of the x-ray fails to coincide with the plane of fracture. Better views may be taken with the fist clenched and the fingers resting on the x-ray plate, with the palm down in extreme ulnar deviation and with extreme pronation (Fig. 2).

If a true fracture is undetected and motion is permitted, absorption of bone occurs along the fracture line, and the fracture becomes more evident in one or two weeks. If the fracture is put rigidly at rest, the process of absorption is arrested and reversed, and union gradually takes place. This is very well illustrated in another of our cases (Fig. 3). In order to rule out all possibility of fracture, it is good judgment to subject every persistently painful wrist to x-ray examination at weekly intervals.

Several classifications of carpal scaphoid fracture have been used in the literature. We prefer the anatomical one. Fractures through the tuberosity are extra-articular and always heal in four to six weeks by bony union—we have treated 1 such case, for the purposes of this discussion, this type of fracture need not be further considered.

FIGURE 3 *Case H E R*

Film A, taken at the time of injury, is negative, film B, taken one month later, shows cystic absorption along the fracture line, film C, taken sixteen weeks after immobilization, shows bony union.

months after the original injury was it reported, when a few symptoms persisted. In 8 cases occurring outside the college the injury was reported to some higher authority (squad trainer, camp doctor or family physician), who incorrectly treated a sprained wrist without taking an x-ray photograph. In 1 case the boy's family physician took an immediate x-ray film, which was negative, yet by the end of six months there had occurred cystic absorption and disintegration into two fragments (Fig. 1).

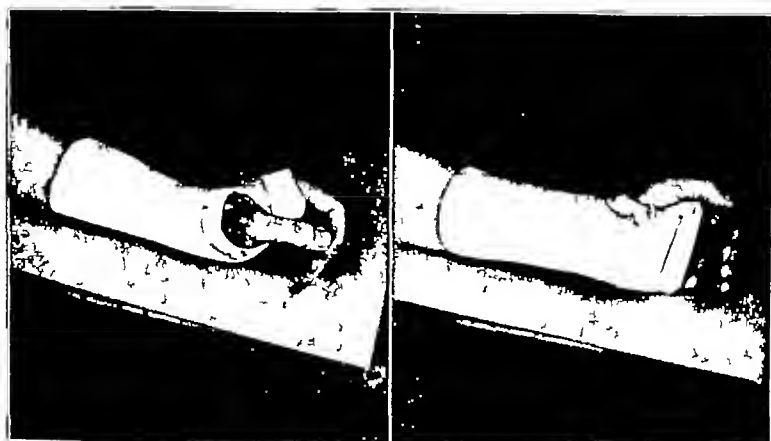

The failure of some of these fractures to be

here. Fractures through the middle and proximal thirds of the body constitute the great majority of injuries. The fresh fractures show little or no displacement. The separation seen later is the result of absorption.

The treatment of acute fractures has been well standardized, and provided that the diagnosis is promptly made and that effective immobilization is instituted and maintained, fractures of the body of the scaphoid unite in a very high percentage of cases. In our series 5 out of 6 such cases (82 per cent) united promptly by bony union, in the

case with non union, the fracture involved the proximal third of the body, and in the cases with union the tuberosity was fractured in 1 and the distal or proximal third of the body in 4 Jackle

of Jackle and Clark² and Hopkins,¹ as well as to our own. There is very definite evidence that the high waist-and-body fractures are not necessarily foreordained to bad results, but that, on the con

A

B

FIGURE 4 The Ideal Type of Cock-Up Splint Using Thermex and Castex as Splinting Materials

and Clark,² with an ideal set up for prompt recognition and early treatment, obtained bony union in 87 per cent of cases. It is certain that early, effective immobilization is the key to good results. Conversely, the motion of five articulating surfaces in frequent movements of the hand is the one

contrary, immobilization gives a high percentage of excellent results.

The optimum anatomical position for immobilization has been carefully worked out by Berlin⁸ in a dissection of 60 wrists, likewise by Soto-Hall and Haldeman.⁹ Uniformly the fragments are

TABLE 1 Data on Cases with Non Union

| CASE | SITE OF FRACTURE | TIME INTERVAL AFTER TRAUMA | PAI | REMARKS |
|----------|---------------------|----------------------------|-------------|---|
| R. G. | Body proximal third | Immediate | None (1 yr) | Law student |
| G. F. | Body middle third | 3 mo | None | Three years army football and hockey |

certain common cause of absorption along the fracture line and subsequent non-union. We can not agree with the advocates of immediate open operation on fresh fractures. Cravener and McElroy⁷ and Adams and Leonard⁷ base their treatment on the premise that simple immobilization treatment results in a high percentage of non unions. This is contradictory to the experience

best apposed with the wrist in 40 to 50° of extension and slight radial deviation. This position has become a fairly standard one. In order further to splint the scaphoid by cradling it between the flexor and extensor tendons of the thumb, Soto-Hall and Haldeman advocate immobilizing the entire thumb. Using a light unpadded cast, we have obtained union without such immobilization.

This greatly increases the utility of the hand during the necessary period of fixation. An ideal material for the usual cock-up cast is the recently demonstrated Thermex splint¹⁰ covered with a light Castex cylinder.¹¹

In our series, 11 fractures were detected from three months to five years after the initial injury (Table 1). We have had an unusual opportunity to follow these cases of non-union intimately over a period of years, and from close personal discussion to evaluate the degree of their disability. One patient was advised elsewhere to have a bone-pegging operation and obtained with operation a good result and bony union. His convalescence was prolonged by a complicating phlebitis. However, today he has a painless wrist, but with marked limitation of motion. None of the other 10 patients considered their symptoms sufficiently bothersome to warrant operation. In some cases there was slight weakness, slight limitation of extension and, to a lesser degree, limitation of flexion at the wrist. Most of the patients had no pain, and all performed very active work. As we have followed these cases year after year there has been, strikingly, no single instance of significant disability because of non-union.

The results of operative treatment of old non-union cases have been good. The operation consists of multiple drilling (Speed,^{4, 12} Edelstein,⁶ Soto-Hall and Haldeman,⁹ or more commonly of inserting a tiny bone peg (Murray,^{13, 14} Burnett,^{15, 16}) through the anatomical snuffbox. Cave⁵ has reported bony union in 4 (57 per cent) of 7 pegged cases, with all cases rendered free from pain and functionally almost perfect. Burnett¹⁶ reports 5 pegged cases, again with good clinical results: bony union in 2, and fibrous union in 3. Murray^{13, 14} reports 16 cases, all with excellent functional results and all united. Comparable results have been reported with drilling. Bohler¹⁷ and Schneck¹⁸ have been able, by very prolonged immobilization (six months or more), to obtain union in these late cases.

From our observation, then, the disability in cases of non-union is rather insignificant and often negligible, even in periods up to five years after the fracture. Hopkins¹ found all his 23 patients able to work as physical directors. We believe that only those patients with definite disability should be urged to have the open operation of bone pegging or drilling. It would seem today that there is no place for the operation of removing both bony fragments. Occasionally removing the proximal fragments does relieve pain, as Cotton¹⁹ so ably demonstrated.

The cause of non-union is related to the degree of motion allowed, not alone to the poor blood supply of the scaphoid. Johnson²⁰ has shown, in a

careful study of experimental fractures of the carpal scaphoid in dogs, that at least in these animals new blood vessels enter both fragments very rapidly, and via a drill hole especially rapidly. Adams and Leonard⁷ found soft tissue interposed between the fragments in one late case of non-union—the first case to be operated on by inlay graft. Because the fresh fractures have slight if any displacement, we believe that soft-tissue interposition is usually secondary, after absorption has taken place.

SUMMARY

Among 6 acute cases of carpal scaphoid fracture, in a series of 17 cases among men of college age, treated with immediate and prolonged immobilization, 5 united. Rigid immobilization should be carried out for twelve weeks, with an additional four weeks' partial immobilization in a supportive gauntlet.

The position we prefer for immobilization is extreme extension of the wrist, with radial deviation and the thumb exposed.

In 11 old cases, either the patient failed to report the injury or the surgeon who first saw the case overlooked the fracture. In order to avoid this, we suggest that every sprained wrist that does not respond to treatment be x-rayed at weekly intervals.

In 10 out of 12 ununited fractures, the disability was so slight that the patients themselves would not admit the necessity of an operation. Seven of these 10 patients participated actively in football and other strenuous sports.

CHANGES IN PUBLIC-HEALTH PRACTICE*

CHARLES F. WILINSKY, M.D.†

BOSTON

NO ACCURATE history of the world's progress would fail to include a most fascinating chapter devoted to the story of man's conquest of disease. Quietly and unobtrusively, without the blare of the trumpet or the beat of the drum, without the stimulus which comes from the flash of the bayonet or the gleam of the sword, many unsung heroes have sacrificed their lives in quest of knowledge, that disease might be conquered, health protected and life extended. The physician and the nurse at the bedside of the sick and in the clinic, the laboratory technician, the sanitarian and other workers in the field of public health have waged constant battles with man's most persistent enemy disease. In ancient times and throughout the so-called Dark Ages, and up to a comparatively recent period, as we measure the slow progress of time, the army of death marched roughshod, exacting its toll of millions of lives. Smallpox, bubonic plague, cholera, typhus, yellow fever, malaria and other diseases played their part in the mass slaughter of human lives.

The dawn of a better day was ushered in less than one hundred years ago by what has been described so aptly as the "Great Sanitary Awakening," this in essence symbolizing an increasing appreciation of the importance of satisfactory environmental sanitation and the great need for better living and working conditions. Students of public health history appreciate in full measure the epochal contributions of the English sanitarians, Simon and Chadwick, and in a marked degree the vision of Lemuel Shattuck here in Massachusetts. The part played by these men and the influence of their efforts marked the beginning of what we conceive to be the modern public-health movement. Shortly after the Civil War the contributions of the immortal Pasteur, of Koch and of their collaborators, scoffed at in a marked degree by the skeptics of that day, crystallized in the acceptance of the germ theory of disease. Increasing bacteriological knowledge, revealing the causes of certain diseases, became an all important factor in the prevention, control and treatment of illness. The influence of Pasteur and Koch reached across the Atlantic to the United States, where Welsh, Pruden Biggs, Park, Sedgwick, Chapin and some of the founders

of the Massachusetts Association of Boards of Health played a part in the formulation of sound public health principles and in the adoption of accepted public health procedures. To the emphasis on environmental sanitation there was added the effort for the control of the communicable disease.

Here in Massachusetts, in accordance with the recommendation of Lemuel Shattuck, included in his epochal report of 1849, the State Board of Health, the first in America, was founded in 1869. The major efforts of health departments for the following two decades were in the field of sanitation and the furtherance of the control of certain communicable diseases. The year 1890, when this association was founded, marked the beginning of twenty five years of uninterrupted tremendous public health progress in America. Among the many significant contributions of this quarter of a century were an appreciation of the importance of the protection of our water and milk supplies, and the development of the procedures by which this might best be accomplished, the contributions of Walter Reed and his colleagues in furthering the control of insect-borne diseases, the utilization of antitoxin in the treatment of diphtheria, the discovery of the carrier as a cause of disease and a source of the spread of infection, and the realization of the importance of sanatorium care in the treatment of tuberculosis, reflected in the establishment at Rutland by the Massachusetts Department of Public Health of the first sanatorium in America. Progress in infant and child welfare, first emphasized by Budin and his associates in France and by Koplik in New York, resulted in the establishment of the first department of child hygiene by the New York Department of Health in 1908. This was preceded by the establishment of school medical inspection in the Boston Health Department in 1894. Campaigns for clean milk bore fruit and this began to be reflected in a reduction of infant deaths. The contributions of Biggs to varied aspects of health administration, the contribution of Park to laboratory practice under municipal auspices, the furtherance of the principles of immunology—these are but some of the outstanding landmarks of what may be termed the most fruitful years in public health history.

What has been done in the quarter of a cen-

*Read at the annual meeting of the Massachusetts Public Health Association, January 27, 1940, in connection with a symposium, "Fifty Years of Progress in Public Health."

†Lecturer Harvard School of Public Health; executive director Beth Israel Hospital; deputy health commissioner City of Boston.

ture from 1915 to today is a familiar public-health chapter to most of us. In retrospect it is fair to emphasize that public health has, indeed, marched a long way since a hundred years ago, a date that marked the beginning of the first social consciousness of the need of a more wholesome sanitary environment, followed by the application of bacteriological knowledge for the control of communicable diseases, and culminating in the present appreciation of the significance of personal and community health.

In 1921, in commemoration of the celebration of the fiftieth anniversary of the founding of the American Public Health Association, a historical volume was published entitled *One Half Century of Public Health*. The period spanned was from 1871 to 1921. The prevalent public-health programs and practices of 1871 were in essence comparable to those of 1890. I should like, therefore, to refer to a statement appearing in the above-mentioned volume written by Stephen Smith, first president of the American Public Health Association. He calls attention in his article to a reply made by a sanitary health official, or health warden, as he was then called, of New York City, functioning in the period mentioned, who when asked, "What do you do when called to a case of contagious disease?" replied "I go to the house and call the people into the street and give my orders to burn sulphur. I never go into the house."

From this unbelievable, superficial and erroneous concept of disease control, which was the practice of that day, public health has indeed traveled far in its onward march, changing the map

by man in the spread of disease. It was recognized that disease was spread by the pollution of water and milk, by insects, by contact with the sick and by carriers, and out of the acceptance of this knowledge developed the modern health program of today.

I believe it opportune at this time to attempt to relate the evolution of the public-health program during the last fifty years to the improvement in health conditions, reflected by the constant reduction of morbidity and mortality, and I shall take the liberty of presenting some vital statistics from the reports of the Boston Health Department. The figures presented are for the year of 1890 and for every decade thereafter. They present a picture of diminishing morbidity and mortality from preventable causes, and also show an increase of those diseases found in middle and later life, a picture familiar to students of vital statistics, who recognize the principle that as we prevent unnecessary deaths among our young, and deaths from preventable causes in other age groups, we produce a very much larger number of people who live to that period of life in which is found an increase of the diseases of adult, middle and later life. The vital statistics of Boston present a reasonable cross-section of prevalent health and disease conditions in many parts of the United States for the periods enumerated, and the mortality rates from specific causes may be considered as typical, by and large, for the country as a whole.

Particular attention is called to the pleasing figures which reveal the halving of the general death rate during the last half-century (Table 1).

TABLE 1 *Death Rates in Boston over a Period of Fifty Years*

of the world for the ultimate good of organized society.

When this organization was first founded, the methods for the protection of our water and milk supplies were exceedingly superficial and unsatisfactory, with a consequent high prevalence of water-borne and milk-borne diseases. Laboratory practices were lacking, and terminal fumigation, now discontinued, was very much the practice of that day. With increasing bacteriological knowledge came the realization of the active part played

by man in the spread of disease. It was recognized that disease was spread by the pollution of water and milk, by insects, by contact with the sick and by carriers, and out of the acceptance of this knowledge developed the modern health program of today.

It is pertinent to relate these progressive improvements to the changes in public-health programs, by a presentation of the practices of 1890 and of the decades that followed, as compared

with those of the present day. In 1890, department of health concerned themselves in the main with environmental sanitation, including increasing efforts for the protection of water supplies, sewage and garbage disposal, abatement of nuisances, fumigation, attempts at control of certain communicable diseases, and terminal disinfection following them.

A study of the annual report of the Boston Health Department for 1890 reveals the expenditure of approximately \$88,000, as contrasted with almost \$1,000,000 spent in 1939. One of the very largest items of the expenditure for 1890 was the cost of disinfection and fumigation, with a record of 93,000 disinfections of cellars, cesspools, alleys and privies, and the disinfection of 4300 rooms, following the presence of highly prevalent contagious disease. This report of the Health Department calls attention to the use of 23,424 pounds of sulfur and 2950 pounds of bichloride of mercury and comments on the recognition of disinfection as one of the recognized factors in the prevention and control of disease. This evident emphasis on sanitation was supplemented by efforts for the isolation of infected persons.

While this tremendous amount of disinfection was going on, 333 out of every 100,000 of our population died from tuberculosis, 103 from diphtheria, 41 from typhoid fever and 9 from scarlet fever. Today the Housing and Sanitation Division performs the accepted necessary public health functions of this important branch of the Health Department service. Soap and water, fresh air and sunlight have replaced fumigation with more beneficial results.

What is the comparative picture? In 1939 we had less than 45 deaths for 100,000 inhabitants from tuberculosis, 0.1 from scarlet fever, 0.4 from diphtheria, 0.4 from typhoid fever. In 1890, with a population of 448,000, as contrasted with the present population of about 840,000, there were actually 400 deaths in Boston from diphtheria, as against 1 this year; 41 from scarlet fever as against 1, 155 from typhoid fever as against 1. If the infant death rate prevalent in 1890 were applied to the number of live births in 1939, we should have had 2600 deaths of children under one, as against 650 actually occurring last year.

In 1900, with a population of 650,000 Boston had 553 deaths from diphtheria, 143 from typhoid fever, 181 from scarlet fever and 1400 from tuberculosis, in spite of the disinfection and fumigation of 13,798 rooms, and the use of 55,000 pounds of chloride of lime and over 6800 pounds of other chemicals.

By 1910 the population had grown to 673,000 people. We had 3453 cases of diphtheria, 2079

cases of scarlet fever, 630 cases of typhoid fever and 1163 deaths from tuberculosis, in spite of the disinfection of 11,744 rooms following contagious disease and 12,358 disinfections for other purposes.

In 1920, with a population of over 750,000 in Boston, which was rapidly approaching its present size, we had 1966 infant deaths, 140 from diphtheria, 71 from scarlet fever, 956 from tuberculosis and 141 from typhoid fever.

By 1930 the Health Department had grown in stature and was spending \$1,000,000 for health purposes, the health units, first conceived locally in 1915, were functioning, tuberculosis clinics had been established on a decentralized basis, the nursing service was extended and generalized, and immunization against diphtheria was being carried on in an extensive way. The tuberculosis death rate had dropped to 69, that of diphtheria to 3 and the infant mortality rate to 70. Dental care was being rendered for 56,000 children. A health educator was employed, and other accepted public health activities had been added to the program of the Health Department.

What have been the results of this half-century of public health effort in Boston as in many other communities where reasonably adequate funds have been provided and expended for the conduct of those activities which prevent disease and conserve health? As already mentioned, the span of life has been materially lengthened, the death rates from all causes have been almost halved, the infant mortality rate reduced by 75 per cent, that of tuberculosis by 89 per cent, and diphtheria and typhoid almost eliminated as a cause of death in our community, while deaths from scarlet fever have become negligible.

What have been the changing practices that have brought about this remarkable improvement? Hermann M. Biggs, to whom we owe a great deal for the furtherance of administrative technique in the field of public health administration, proclaimed that public health was purchasable, and that within reasonable limitations communities might determine their own death rates. What did he mean by that? He meant in substance that the wise expenditure of adequate funds for the conduct of essential public health activities would markedly control the prevalence of preventable diseases and deaths from many causes. What are these activities that he had in mind, and what part have they played in influencing the health of the American people? Allusion has already been made to the significant effect of the application of sound procedures for the sanitation of the environment, the protection of our water and milk supplies and the control of communicable diseases. The place

of the laboratory as a significant component part of a modern health department has been amply demonstrated. The significance of immunological agents has been demonstrated beyond measure as a factor in the prevention of disease.

Very fortunately for organized society, this century has been marked by a number of significant public-health movements which have required the participation of the individual. The child-hygiene movement, the campaign for the control of tuberculosis, the mental-hygiene movement and the social-hygiene movement, waged by official and voluntary agencies, have stimulated the imagination of the American people, and have resulted in higher standards of individual and community health. Clinics of various types, carrying on the functions in the above-mentioned fields and having for their objectives the prevention and control of disease, have become increasingly utilized by armies of people, who have demonstrated by their reaction that they truly believe that an ounce of prevention is worth a pound of cure.

The progress in the field of child health has justified the frequently expressed belief that we are living "in the century of the child." Allusion has already been made to the effort in France for infant welfare and of the work in New York City on infant feeding by Koplik, who in the late eighties and early nineties stressed the significance and importance of breast feeding and clean milk. There developed at the beginning of this century increasing interest and programs for the conservation of the lives of our young children, in so marked a degree that we now proclaim the infant mortality rate to be an index of a community's intelligence. This implication is based on the premise that we may safeguard the lives of our children and prevent unnecessary deaths among the young by the development and maintenance of adequate programs for the conservation of child life.

It is important to call attention to the significant relation between satisfactory prenatal care and maternal and infant welfare. Studies carried on in Boston, in Philadelphia and by the Maternity Association of New York have proved that the death rate among expectant mothers receiving adequate prenatal care was about half that among those lacking such medical supervision. A study of 1000 maternal deaths, conducted by Dr. Susan Coffin for the Massachusetts Department of Public Health, revealed the absence of adequate prenatal care among 890 of these expectant mothers. Today in every intelligent community reasonably adequate services exist for prenatal care, either in the offices of the medical profession or obstetrician

or in organized clinics under the auspices of the health department or private agencies. Prenatal care has done much to reduce the hazards of the toxemias of pregnancy, injuries at birth and prematurities, and to lower deaths among infants. There is, however, much room for further improvement in deaths occurring during the first month of life.

Both voluntary and official agencies have concerned themselves with the problem of infant, preschool and school-child health. Milk stations and baby and preschool clinics have served as the headquarters for the dissemination of information, and for the education of mothers as to the very best methods for keeping well children well. Among the administrative methods for the conduct of this work has been a co-operative plan developed in Boston between the Health Department and the Harvard, Tufts and Boston University medical schools, whereby pediatricians from the teaching staffs man the clinics and are reimbursed by the Health Department. Advantage is taken of the presentable opportunity for teaching medical students preventive pediatrics. It is in the fields of child health and tuberculosis that the public-health nurse has made a lasting contribution.

Newborn babies are visited shortly after birth by nurses of the Health Department, and mothers are urged to take their babies either to their own family doctor or to the organized clinic for periodic medical supervision. Here children are examined, vaccinated against smallpox and immunized against diphtheria. Breast feeding is stressed, and wherever possible the use of pasteurized milk and the preparation of the proper formula are taught. When children arrive at the preschool age, the so-called neglected age, every effort is made to maintain the continued interest of parents in the physical and mental health of the child. There is, however, room for much further progress among this age group.

We are familiar with the frequency with which we find faulty teeth, defective vision, defective hearing, malnutrition, faulty posture, functional or organic heart disease and occasionally tuberculosis among our school-child population. Large sums are being spent in the United States for the medical inspection of schools and physical examinations for the discovery of remediable defects. Emphasis should be placed on the importance of increasing our efforts in the direction for the correction of defects found. An example of excellent service in this field is the program carried on by Dr. James Keenan, his school physicians and nurses, in the Boston public schools, while the Health Department assumes the responsibility

for medical inspection in the parochial schools

The care of the mouth and primary teeth is receiving fitting recognition. The Forsyth Dental Infirmary in Boston, the Eastman Clinic in Rochester, New York, and the Guggenheim Clinic in New York City are outstanding examples of endowed institutions concerning themselves with prophylactic dental care. It is hoped that what is being done for children today in the way of preventive dental care may bring about higher standards of dental health for the American people. An outstanding example of municipal interest in this field is the program of the Boston Health Department, whereby a corps of approximately twenty dentists and ten hygienists of the Forsyth Dental Infirmary carry on prophylactic dental service in the health units maintained by the city. This personnel is reimbursed from tax funds.

Attention is being given to the subject of proper nutrition as a factor in normal growth and development, to the eradication of faulty food habits and to the establishment of proper and well balanced diets, and a keener appreciation is being shown of the significance of the vitamins.

The attack against tuberculosis represented what may be termed the second public-health movement at the beginning of the present century. The persistence of Trudeau established the philosophy of sanatorium care. The voluntary agencies in this field not only did much to lay the foundation for a better understanding of the methods by which tuberculosis might be controlled but also in the formative years conducted clinics for diagnosis and treatment. Case finding, the isolation of the infected person, the rounding up of contacts who have been exposed, occupational adjustments and pneumothorax are all a part of the modern campaign for coping with this problem. Today every health department of appreciable significance either maintains, or sees to it that there exist in the community, adequate facilities for tuberculosis control.

For a number of years the subject of the control of venereal diseases was approached, except in rare cases, with much diffidence and hesitancy. Gonorrhea and syphilis represent an important public health problem. Stimulated by the efforts of the National Society for Social Hygiene and more recently by the vigorous challenging efforts of Surgeon General Parran, and with the assistance of federal funds, a worth while program is constantly making further progress. The Massachusetts Department of Public Health, with the aid of the above mentioned funds, not only assists in the maintenance of a number of venereal disease clinics but stimulates the upholding of adequate standards. Of particular significance is the organiza-

tion of facilities for rounding up the lapsed cases in this field.

As the clock of time has advanced during the present century, there has been increasing recognition of the relation of housing to health and to the control of disease. We have recognized that adequate light, air and ventilation and the avoidance of overcrowding are minimum requirements in the field of human needs.

Massachusetts, as in many other directions, blazed the way in the formulation of necessary legislation for the protection of the health of its workers. Provisions for factory inspection, minimum hygienic standards in places of employment, protection against the hazards of industry and workmen's compensation are but some of the safeguards in effect today. The sanitary inspector has a vital place in the public health program, although some of his activities have changed in character.

There is a need for increasing recognition by those responsible for community health of the problems of mental hygiene and mental disease. A ray of hope is offered by the expansion of the child-guidance clinics conducted under official or voluntary auspices, which deal with the problem of faulty habits in children and the need for the correction of the environment to which the child is exposed. Certainly the tragically high prevalence of mental disease should focus attention on the need of more prevention.

Allusion has already been made to the fact that we are living in an era in which the emphasis is on personal health. Vigilant health officers appreciate the value of an understanding by the public of the functions and objectives of the health department. Healthful living needs interpreting in simple, understandable language. The spoken word in the clinic, in the lecture hall and over the radio, and the visit of the public-health nurse, can be opportunely utilized for educational health propaganda. The leaflet, the poster, the pamphlet may all serve the useful purpose of making people more health minded. Here and there health educators employed by health departments are living examples of changes in public health practice from police methods to education.

As deaths from preventable causes have been lessened and the average span of life increased, a large proportion of our population are living to middle and later life, with a consequent increase of the diseases prevalent in the older groups. Among these illnesses are cardiovascular disease, cancer and diabetes. This newer public health problem should be the concern of the health officer. While this does not imply that he must necessarily conduct medical activities for the treatment of these diseases, it is his obligation both

to educate the public as to methods for their contact, and to see that there are in his community an organized medical profession, and clinics and hospitals to cope with these problems

The health officer today integrates the efforts of administration—the findings of the statistician, the medical inspector, the public-health nurse, the milk and food and sanitary inspector, the laboratory technician and the school physician—with those of the representatives of the voluntary health agencies. Today, in cities of varying size, health services are frequently conducted on a district basis. Radiating out of health centers, founded to bring together under one roof in a spirit of service and of team play all concerned with the problem of health and welfare, these services attempt to present a united front against sickness and death.

Statistical figures appearing in this effort to point out improvements in health because of changes

in public-health practices tell but a part of the story. We can do much better. There are still too many deaths from preventable causes. We can add more years to the span of life, since we have knowledge and methods at our disposal possessing rich lifesaving values. We must create by education and by the conduct of adequate programs a greater desire on the part of everyone for life's most treasured possession, vigorous physical and mental health. With an appreciation of the dryness of figures, I close with the words of Dr. Charles V. Chapin, to whom all those interested in public-health progress owe so much.

Figures do not measure the terrors of epidemics, nor the tears of a mother at her baby's grave, nor the sorrow of the widow whose helpmate has been snatched away at the prime of life. To have prevented these not once but a million times justifies one half century of public health.

330 Brookline Avenue

BOSTON MEDICAL LIBRARY

Report of the Librarian for 1939

DURING 1939, the Boston Medical Library enjoyed an exceptional year. It was used by over 10,000 persons. Thirty thousand books or pamphlets were spread before those individuals, in other words, about 10 per cent of the 300,000 items left the library shelves to fulfill their designed purpose, that of transmitting men's ideas as recorded on the printed page to the present generation. Some of the 30,000 spoke the language of yesterday, many the current verbiage of our day. Old, middle-aged, adolescent or infantile, all gave to the reader, one hopes, a source of inspiration to write better his own words or to treat more efficiently the sick who came under his care. To serve 10,000 persons in a year is no mean task, to serve them well is the standard set by the Boston Medical Library. The continued support of old members and the influx of new members in 1939 indicate that the library has maintained its standard and served its purpose.

Periodicals

As noted in last year's report, one of the important functions of the Library is to maintain for reference the current periodicals that contain the essence of contemporary medical thought. In 1939 the library increased the number of periodicals to 822, still falling short of the 1937 record of 907. We have thus added to our collection in the last year, and by adjustment with neighboring libraries have provided to the Boston medical area most of

the journals likely to be called for by our readers. As the rarely sought periodical can be made available in a few days from libraries outside Boston, we believe that our needs were well met. Unfortunately our funds have prevented us from binding as many journals as we desired—only 584 volumes in 1939, as compared with 737 in 1938 and 900 in 1937. In spite of this, the journals are reasonably well preserved in temporary binders and will not suffer for some years. The librarian tenders his thanks to the members and organizations that contribute periodicals. Not a few of our state journals and many others are received from the *New England Journal of Medicine*. Many local medical societies have again come to our aid in helping to pay for foreign periodicals.

Books

Our main source of new books continues to be, fortunately for the library, the *New England Journal of Medicine*. These, a total of 335, were reviewed in 1939 by our generous members and a large proportion turned back to the library. To the reviewers the library is again greatly indebted. By their kindness the library maintains a current file of books, funds for the purchase of which are not at hand. A few new books come from other sources—donations from library members, gifts from authors and review copies from the *Bulletin of the Medical Library Association* and the *Journal of Bone and Joint Surgery*. These books are con-

stantly in demand and are fulfilling a need, especially for students. Our book funds allow for the purchase of replacements and a few books not received by the Book Review Department

Rare Books and Books of Reference

To the Bullard and Hyams collections a few items have been added. The funds are nearly used up and only occasional purchases can be made. The collections are being used and correlated with similar collections elsewhere. We are constantly in touch with the Rare Book Room at the Harvard College Library and with the Boston Public Library. Additions to our books are known to others and we, in turn, keep in touch with the activities of our neighbors. We look at the problem in a broad manner, refuse to compete or duplicate and always keep in mind the growth of medical and scientific literature in Boston and its vicinity. To the true scholar, a book near at hand is practically as valuable as a book at hand. The *Union Catalogue* now nearing completion, is his most valuable asset.

Our stock of reference books is constantly maintained and augmented. Money spent for this type of book is money well used, items of reference soon become rare, almost never obsolete. Our error is usually that of not buying enough copies when issued, with covers worn off and dog-eared pages, how often we wish we had a second, fresh copy as the years pass. The Harvard College Library, the Boston Public Library and the Massachusetts Historical Society aid us in acquiring the more expensive and rarely used reference books. Our collection is surprisingly complete, however, thanks to the director's long interest in books about books and the indispensable material that subjoins a superb collection of fifteenth-century books. Rarely does one have to step outside our door to identify a rare book catalogued by a dealer.

The director's wide acquaintance with book sellers and their wares brings not a few choice items to our attention before they go into the general market. Our purchases have with increasing regularity, become of the over-the-counter type, an advantage to both seller and buyer.

A paper on "The Plague Tracts in the Boston Medical Library" has recently been completed by the director and the librarian. The library has 30 items published before 1501 listed by Klebs and Sudhoff and 4 additions, including a *Pestblatt* unique in character. The Bullard and Hyams collections thus furnish material for research. Some of the additional books are described for the first time in literature. Klebs's *Short Title List* the value of which was pointed out in the

1938 report, has again been used as a basis for describing the books.

A visit to the Scandinavian countries during the summer, just before the outbreak of the war, enabled the librarian to renew old acquaintances, make new friends and purchase a number of items for the library. Important reference books on Danish, Swedish and Norwegian medicine were added to our collection and one incunabulum was acquired. The rare item was the *Naparsuma sonut Ikjortiksut* one of three known copies of the first medical book printed in Greenland. The book in the Eskimo language, was set up on a hand press and printed in 1856. It is one of the earliest books printed in Greenland and describes the diet provided for the sick and the care of open sores. A friend in Copenhagen has made an English translation, and plans are under way to publish the small volume in facsimile, with an English and Danish translation. Vilhjalmur Stefansson, the Arctic explorer, has shown great interest in the book, and because of his well known knowledge of the dietetics of the Eskimo it is expected that he will write an introduction. When purchased, it was thought that our copy was the only survivor except for the one in the Royal Library at Copenhagen. A third copy, however, has been found in the Krabbe Library,¹ now at Stanford University.

In 1929, the director² catalogued 179 items in the Bullard Loan Collection. With the passing years the collection has more than tripled. A new catalogue is badly needed, and it is hoped that funds will not long be delayed for assessing this remarkable group of books and placing the results in printed form. Much of the work on such a catalogue has already been done.

In contrast to the fifteenth-century collection in the library, separately housed, the books published in the sixteenth century, usually grouped in a section of books issued between 1501 and 1640 were widely separated on our stacks at the beginning of the year. Stimulated by *A Bio Bibliography of XVI Century Medical Authors* by Dr. Claudius F. Mayer, specimen pages of which were issued with Volume IV of the Fourth Series, *Index-Catalogue of the Library of the Surgeon General's Office* (1939) and by the interest in these items manifested by the Harvard College Library, we have begun to shelve this valuable group of books, particularly the English imprints in Holmes Hall. They are separately classified, the English items being checked with Pollard and Redgrave's *Short Title Catalogue*.³ This practice is in keeping with the accepted procedure in the large libraries. In addition special groupings of Americana are being made, as well as travel

to educate the public as to methods for their contact, and to see that there are in his community an organized medical profession, and clinics and hospitals to cope with these problems

The health officer today integrates the efforts of administration—the findings of the statistician, the medical inspector, the public-health nurse, the milk and food and sanitary inspector, the laboratory technician and the school physician—with those of the representatives of the voluntary health agencies. Today, in cities of varying size, health services are frequently conducted on a district basis. Radiating out of health centers, founded to bring together under one roof in a spirit of service and of team play all concerned with the problem of health and welfare, these services attempt to present a united front against sickness and death.

Statistical figures appearing in this effort to point out improvements in health because of changes

in public-health practices tell but a part of the story. We can do much better. There are still too many deaths from preventable causes. We can add more years to the span of life, since we have knowledge and methods at our disposal possessing rich lifesaving values. We must create by education and by the conduct of adequate programs a greater desire on the part of everyone for life's most treasured possession, vigorous physical and mental health. With an appreciation of the dryness of figures, I close with the words of Dr. Charles V. Chapin, to whom all those interested in public-health progress owe so much.

Figures do not measure the terrors of epidemics, nor the tears of a mother at her baby's grave, nor the sorrow of the widow whose helpmate has been snatched away at the prime of life. To have prevented these not once but a million times justifies one half century of public health.

BOSTON MEDICAL LIBRARY

Report of the Librarian for 1939

DURING 1939, the Boston Medical Library enjoyed an exceptional year. It was used by over 10,000 persons. Thirty thousand books or pamphlets were spread before those individuals, in other words, about 10 per cent of the 300,000 items left the library shelves to fulfill their designed purpose, that of transmitting men's ideas as recorded on the printed page to the present generation. Some of the 30,000 spoke the language of yesterday, many the current verbiage of our day. Old, middle-aged, adolescent or infantile, all gave to the reader, one hopes, a source of inspiration to write better his own words or to treat more efficiently the sick who came under his care. To serve 10,000 persons in a year is no mean task, to serve them well is the standard set by the Boston Medical Library. The continued support of old members and the influx of new members in 1939 indicate that the library has maintained its standard and served its purpose.

Periodicals

As noted in last year's report, one of the important functions of the Library is to maintain for reference the current periodicals that contain the essence of contemporary medical thought. In 1939 the library increased the number of periodicals to 822, still falling short of the 1937 record of 907. We have thus added to our collection in the last year, and by adjustment with neighboring libraries have provided to the Boston medical area most of

the journals likely to be called for by our readers. As the rarely sought periodical can be made available in a few days from libraries outside Boston, we believe that our needs were well met. Unfortunately our funds have prevented us from binding as many journals as we desired—only 584 volumes in 1939, as compared with 737 in 1938 and 900 in 1937. In spite of this, the journals are reasonably well preserved in temporary binders and will not suffer for some years. The librarian tenders his thanks to the members and organizations that contribute periodicals. Not a few of our state journals and many others are received from the *New England Journal of Medicine*. Many local medical societies have again come to our aid in helping to pay for foreign periodicals.

Books

Our main source of new books continues to be, fortunately for the library, the *New England Journal of Medicine*. These, a total of 335, were reviewed in 1939 by our generous members and a large proportion turned back to the library. To the reviewers the library is again greatly indebted. By their kindness the library maintains a current file of books, funds for the purchase of which are not at hand. A few new books come from other sources—donations from library members, gifts from authors and review copies from the *Bulletin of the Medical Library Association* and the *Journal of Bone and Joint Surgery*. These books are con-

was to send to the library a gift of money to preserve the books of Oliver Wendell Holmes.

The co-ordination with other libraries continues in the past. New advances have been made in the exchange of material with the library of the Harvard Medical School. Our collection of theses is now largely catalogued. An informal committee has met occasionally to consider the broad vista of the medical library situation in Boston. Opinions are being formed which may be of considerable value in the future in regard to whatever problems have to be met.

Finally, the librarian again calls the attention of the members to our devoted, small staff. Without unusual personnel our library could not function with the small number of people employed. Even so, the library could use double the force and still not fulfill its most desired purpose. For the present, however, the year has passed without serious complaint and with much generous praise.

The librarian knows how richly the praise is justified. The public, students, members and guests all come to our doors. Rarely does one leave without a realization that the Boston Medical Library plays an important part in the medical and cultural life of Boston. May it never play a lesser role!

FEVER THERAPY IN ALLERGIC DISEASE

ROBERT W. HYDE, M.D.*

FAIRFAX, VERMONT

FEVER has been used as a therapeutic agent in bronchial asthma since 1931. Favorable results of varying degree have been reported by Fenberg, Osborne and Steinberg,¹ Halphen and Audclair,² Sheldon,³ Phillips,⁴ and others. The technics have been varied, with temperature elevations varying from 101 to 107°F, durations from forty five minutes to eight hours and the number of treatments from one to fourteen. In my cases of bronchial asthma less fever was found necessary than in those reported by other workers, so that although the series is small, I feel justified in reporting it.

Owing to the fact that the high temperatures that were first thought necessary for therapeutic effect constituted an excessively severe treatment for hay fever and urticaria, very few reports of this type of treatment in such conditions have appeared. Le Boutillier⁵ mentions favorable results in 5 cases of hay fever. Trautman⁶ reports negative results in 2 cases of hay fever, and favorable results in 1 case of urticaria. Litterer and Phillips⁷ report favorable results in 80 cases of urticaria. Hence I believe that the hay fever cases presented here are a worthwhile addition to the reports on the subject.

Fever therapy was administered in 32 cases of

*Superintendent, Mount Mansfield Sanatorium, Fairfax, Vermont.

allergic disease. These were selected from about 100, seen over the same period of time, because they had not responded to simpler methods of treatment. No attempt was made to distinguish the different etiologic factors in the cases of bronchial asthma and hay fever that were treated. Nor is any attempt made to explain the rationale of therapeutic fever in allergic disease. I merely wish to show the results obtained from a certain minimal amount of fever treatment in these cases.

TECHNIC AND MANAGEMENT

In the technic used, all fever treatments consisted of elevating the patient's temperature to not over 103°F (axillary) for not longer than one hour. The majority of treatments consisted merely in elevating the temperature to 102°F in twenty five minutes, with immediate termination of the treatment, allowing the temperature to subside gradually to normal. This degree of fever is less than that reported by any authority except Phillips⁴ and Le Boutillier,⁵ and the duration is less than any other reported.

All fevers were induced in a humidified external heating type of cabinet. No claim is made here for the superiority of one type of fever induction over another, so long as the method

used can be properly controlled and can produce a rapid induction of fever

Care was taken in all cases to supply abundant fluids in the form of saline and glucose, so as to prevent bodily depletion. All premedication, preparation and supervision were conducted along recognized lines,⁸ except that no sedation was given before or during fever, other than 40 gr of sodium bromide to certain apprehensive individuals

Bronchial Asthma

In patients with asthma, the management consisted in administering one treatment daily until what was considered to be a primary response to

Table 1 shows the results of treatment in the cases of bronchial asthma. The statements as to the clinical improvement are based on the follow-up history, and on short periods of observation only of such patients as had subsequent attacks of sufficient severity to require calling a physician. No prolonged period of hospital observation was possible before or after treatment.

In Case 1 the patient obtained only temporary relief from fever therapy, but after tonsillectomy he improved clinically. In Case 3 the patient received a course of carbon-arc ultraviolet treatments in addition to fever therapy. In Case 13 the patient received "cold" vaccine throughout the following winter. In Case 15 the patient was

* Usual signifies that the patient had been under good general medical management with little specialized treatment.

† Thorough signifies that the case had been thoroughly studied and treated from every conventional angle in a good hospital.

‡ Dashes are used when the treatment did not extend over the time mentioned or the therapy specified was not used.

§ Usual signifies no change in the interval between attacks.

fever had been obtained. This response consisted in a decrease of bronchospasm, increase of moist rales, a productive cough and the subjective feeling that the attack was beginning to subside. The patient was instructed to return immediately if the improvement did not continue. An additional treatment was given in three days, if the attack was not completely terminated by that time. The schedule for further treatment consisted of instructing the patient to return on the first sign of an oncoming attack, when therapeutic fever was administered at any time of day or night after one hour's preparation of the patient.

No attempt was made to subject the patient to fever therapy when entirely symptom-free. As will be seen, the response to fever was so varied that I did not consider it justifiable to lay out any arbitrary course of treatments, but rather sought to individualize each case.

instructed in and performed chest exercises. In the last three cases the concurrent treatment was thought to be only contributory to the results obtained. No other patients received treatment that could have been responsible for the clinical improvement they exhibited.

As shown by the table, 20 patients with bronchial asthma received an average of two and a half treatments in one year. Twelve had clinical remissions of three to ten months. This was in addition to whatever spontaneous remissions were usual in their cases. The remissions were followed by attacks of decreased severity, frequency and duration. Three other patients were clinically improved in that the attack terminated more abruptly and the subsequent attacks were less severe. Hence a total of 75 per cent of the cases showed clinical improvement. No case was asymptomatic one year following treatment. Seven of

12 patients under observation the second year had attacks that responded so easily to home medication that they no longer returned for fever or sought other medical advice.

Four patients who had been unable to obtain relief with adrenalin in any form for several years prior to fever therapy were able to obtain satisfactory relief for at least one year after therapeutic fever. No attempt was made to explain this, or to determine whether it was true of all cases improved by fever.

A variation was observed in the time and type of primary response to fever therapy when it was administered during the asthmatic attack. Although there are an insufficient number of cases to allow any definite conclusions, the fact that the response occurred at any time from the induction stage of the fever session until twenty-four hours later is worthy of note. In a few cases the attack

TABLE 2. Immediate Results of One Fever Session in an Attack of Bronchial Asthma (by Number of Cases)

| Condition | DURING FEVER | 1-3 hr. | AFTER FEVER 3-6 hr. | 12-24 hr. | 24-48 hr. |
|-----------|--------------|---------|------------------------|-----------|-----------|

| No change | 8 | 10 | 6 | 5 | 9 |
| Worse | 5 | 0 | 4 | 0 | 0 |

terminated with so little productive cough that it was a surprise to the patient.

As shown in Table 2, in 11 cases only one treatment was needed to cause a remission. Of the re-

Hay Fever

The following cases of hay fever were observed frequently throughout the season, so that the follow up is reliable. The management of the cases in no way differed from that of those of bronchial asthma. In hay fever the primary response to fever was considered to be a decrease in conjunctival irritation and in edema of the nasal mucous membrane. The treatments were repeated until this result had been obtained to a lasting degree.

No concurrent specific desensitization treatment or local or general use of vasoconstrictors was permitted. The patients made no attempt to avoid offending pollens while under treatment or subsequent observation. The only concurrent treatment was the oral administration of calcium in cases where the patients did not drink milk, and the giving of potassium chloride, 5 gr. three times daily, when mild or transient symptoms were apparent the third season, the latter occurred in 4 cases in which marked improvement had been shown the second year.

Nine of 11 cases (81 per cent) treated showed clinical improvement (Table 3). One case was asymptomatic one season following treatment, and 2 were asymptomatic for two seasons following treatment. Two patients had symptoms so mild and transient that they did not seek medical attention. Four patients had mild symptoms the third season, for which they took potassium chloride, as mentioned above.

TABLE 3. Data on Cases of Hay Fever

| Case No. | Duration | Result of Desensitization | Severity | Number of Fever Treatments | | | Asymptomatic | Improved |

Dashes indicate that no desensitization had been done.

†Dashes signify that the patient was not under treatment at the time indicated.

maining 9 cases that showed no change from twenty-four to forty-eight hours after fever, a second treatment was necessary in 3 cases and a third treatment in 2. In Case 13 the patient, who had been constantly asthmatic for eighteen months, received one fever session every other day and obtained no relief until after the fourth session when she had a complete remission. In 3 cases there was a relapse after obtaining a primary response to fever.

The number of cases treated were insufficient to permit material conclusions as to the primary response in hay fever. All the patients treated exhibited some transient improvement immediately afterward, but in several this was not sufficient to be considered a remission. This cannot be explained on the basis of dehydration or change in acid-base balance, as care was taken to prevent any such change. In 4 cases only one treatment was necessary, in 4 two treatments and in 1 three.

Three patients had a remission after a primary response

Chronic Urticaria

One case of chronic urticaria was treated. A sixteen-year-old girl, who had suffered for three years from severe bronchial asthma and hay fever, the latter of which at the time of treatment was partially controlled by eliminative diet and specific desensitization, also suffered from urticaria of eight months' duration, which was present daily, and much worse at night.

The first fever treatment was given February 25, 1939, and was followed by a remission of the urticaria for five days, and then a recurrence worse than before. The second fever therapy on March 8, 1939, was followed by remission of the urticaria for seven months. Hay fever was slight or transient through the 1939 season. There was complete remission of the bronchial asthma for four months, and only mild symptoms were noted the subsequent seven months.

REACTIONS TO FEVER

Although no attempt is made to interpret reactions, what was considered to be such was noted in 6 cases. This fact is mentioned here merely because it may prove to be of significance in determining the mechanism of the effect of therapeutic fever on allergic disease.

Four patients with bronchial asthma experienced very severe attacks three to six hours following the fever session, after they had received some primary relief. One patient with hay fever, sensitive to timothy, ragweed, goldenrod and paintbrush, developed urticaria over all exposed areas of the body while working in a hayfield the day following fever therapy. No previous history of urticaria in this case was obtained. The patient suffering from chronic urticaria developed an acute attack during the fever session while the temperature was subsiding to normal. For some reason the lesions did not itch.

DISCUSSION

No claim is made as to the cure of bronchial asthma or of any other allergic condition with fever therapy. In fact, none of the cases of bronchial asthma reported here were asymptomatic when observed one year after the treatment. Owing to the fact that most workers have used far different technics with no comparative study, the optimal technic of administering therapeutic fever in allergic conditions is yet to be determined. Phillips and Shikany⁹ considered a minimal course of ten treatments necessary, with fifteen treatments preferable. Feinberg, Osborne and Steinberg¹ administered a course of two intermediate

fevers, sometimes repeating them in case of relapse. Phillips's results seem superior to those of the latter workers, but it must be considered that they were dealing only with intractable cases. Miller and Piness¹⁰ obtained only temporary relief in 2 out of 7 cases, using one fever session.

None of the cases in this report received as many fever sessions as were considered desirable. Because of lack of co-operation of some of the patients, no opportunity was given to treat any subsequent light attacks or to continue therapeutic fever until the patient was in improved general health. There is reason to believe that the results would have been better if more fever sessions could have been administered. This belief is based on the fact that marked improvement was obtained in 7 of the 8 cases of asthma receiving three fevers or more, and that Cases 5 and 15, which were exceptionally severe and received the most treatment, have exhibited the most complete improvement. Both these patients had been entirely incapacitated for work for over eight months prior to fever therapy, and have been able to carry on their work for one year and two years, respectively, subsequently. This opinion as to the optimal number of fever sessions is in agreement with the conclusion of Phillips.

As to the type of fever session most efficient in the treatment of allergic disease, the most unfavorable reports seem to come from those using long, high fevers. Trautman⁸ reported no improvement in 5 cases of bronchial asthma treated at 104 to 106°F and in 2 cases of hay fever treated at 103 to 104°F for five hours. Five treatments were given, so that the results can not be attributed to too few fever sessions. Metz¹¹ obtained relief in 3 of 8 cases with a fever of 106°F for three hours. Phillips and Shikany⁹ reported in 1935 "Temperatures above 105°F really have no advantage over those ranging between 102 and 105. Temperatures sustained for four hours produce results comparable to those extending over longer periods." In 1936 Phillips⁴ reported that he was treating a group of patients with fever of 101 to 102°F for forty-five minutes; he considered this technic satisfactory. Le Boultelier,⁶ using fevers of not over 103°F, reports uniformly favorable results in 9 cases of bronchial asthma and 5 cases of hay fever.

It would seem rational to expect that the strain of the high fever on the asthmatic patient, already struggling for breath and debilitated by his prolonged attack, would partially counterbalance any beneficial effect that an induced fever might have on the condition.

I have tried several types of fever elevation in bronchial asthma, although in too few cases to

furnish any definite conclusions, but enough to give the impression that short elevations of temperature to 102°F give results at least comparable with, if not superior to, those obtained with higher and longer fever sessions. In addition there are the added advantages of the reduced strain, the lessened danger and the greater economy of the lower fever. It is possible to treat many aged arteriosclerotic patients for whom higher fevers would be contraindicated. Conditions such as hay fever, urticaria and eczema, which one would be reluctant to subject to a high or intermediate fever, can be treated. The cost of fever is so reduced that the short low fever technic can be used with patients who would be unable to afford the costly long high fever technic.

These cases demonstrate the facts that a certain amount of lasting improvement can be obtained in many cases of allergic disease from a small number of low fever sessions, and that this technic may be found useful where conditions make it difficult to administer what is considered to be the optimal number of fever sessions.

SUMMARY

A total of 32 cases of allergic disease were given

therapeutic fever in a humidified external heating type of cabinet.

The results with a small number of short low fever treatments correspond favorably with those obtained with a greater number of longer and higher fevers, in that 75 per cent of the asthma cases and 81 per cent of the hay fever cases showed clinical improvement.

REPORT ON MEDICAL PROGRESS

TUBERCULOSIS

DONALD S. KING, M.D.*

BROOKLINE, MASSACHUSETTS

IN MASSACHUSETTS in 1939 there was again a drop in the death rate from pulmonary tuberculosis. The unofficial figure for that year is 33.8 per 100,000 population, as opposed to 34.9 in 1938 and 40.0 in 1937. Figures from other states are not yet available. There is, however, an interesting report from the Metropolitan Life Insurance Company¹ showing that in its group of industrial policyholders in 1939 the tuberculosis death rate was 44.9, a 4.9 per cent decline for the year. This rate was a little more than half that recorded in 1929 and one fifth that of the company's first report in 1911.

CONTROL PROGRAM

The years are bringing changes in the methods for hastening the decline in the morbidity and mortality of pulmonary tuberculosis. At one time it was believed that pulmonary tuberculosis was

always contracted in childhood, and that it was such childhood lesions that flared into activity later in life. Efforts were therefore directed principally toward finding infected children and treating them in outdoor schools and preventoria in the hope that their lesions could be so securely healed that they would never again become active. We have learned much from studying large groups of school children, and thousands of people have been taught the principles of hygiene in summer camps and preventoria. With the decline in the incidence of tuberculosis, however, so few cases of active disease are now found in a whole state study of young school children that the results in many sections of the country do not justify the expense. A survey by Remick and Chadwick² in Middlesex County disclosed that in 1938-1939 it cost \$3500 to discover each case of active disease in the school clinics. These clinics have therefore been discontinued and more attention is being paid to the study of contacts of sanatorium pa-

*Associate in Medicine, Harvard Medical School; associate physician, Massachusetts General Hospital.

terested in first infections, and has asserted repeatedly that "the primary complex as it develops in the body of an adult is a benign disease and apparently is of no more clinical significance than the primary complex which develops in the body of a child." In substantiation of this statement he and his associates report a group of 557 nurses and medical students who became reactors to tuberculin while under observation, none of whom developed active pulmonary tuberculosis.

Myers's contention has been challenged by a number of authorities in this country and abroad. In a letter to the *Journal of the American Medical Association*, Malmros,¹⁷ of Sweden, has recently objected to it. He agrees that in the great majority of cases the lesions are asymptomatic and do not progress to manifest disease, but he maintains that "in a considerable number of cases the initial apical lesions were the first manifestation of a progressive type of pulmonary tuberculosis" and that it is not safe to consider the infection benign just because it is primary.

Malmros's observation was borne out by Badger and Spink's¹⁸ study at the Boston City Hospital, in which they noted 7 cases of primary infection with x-ray lesions occurring among student nurses. Of these cases 3 never developed symptoms, 2 became arrested with sanatorium care and 2 progressed in spite of sanatorium treatment.

It seems evident, therefore, that one must not be too much influenced in prognosis by whether the infection is primary or secondary, but must take all the other factors into consideration in planning treatment.

One of the difficulties in this whole problem has seemed to me to be that writers have spoken of the primary infection as if it were a single infection occurring in a non-sensitized individual. They have not considered the facts that in almost every case there must be repeated exposure and that since sensitization develops within three weeks from the first exposure many of the infections must be on a sensitization basis and, therefore, of the reinfection type. The size and frequency of the dose of tubercle bacilli and the interval between exposures must necessarily play important parts in determining the nature of the lesion.

CHEMOTHERAPY

Some years ago Wells and Long¹⁹ pointed out the theoretical difficulties involved in the chemotherapy of pulmonary tuberculosis in human beings. It is necessary to find a chemical that will not only kill tubercle bacilli in vitro but will also prove itself capable of penetrating an avascular tubercle, enter the phagocytic cells within the tu-

bercle and kill the "wax-armored tubercle bacilli" in the phagocytic cells. This is a great deal to expect, and laboratory research has shown that sulfanilamide and sulfapyridine do not meet the requirements. If the development of a tuberculous lesion is to be inhibited in laboratory animals, these drugs have to be given in seven times the usual clinical dose, and treatment must be started a number of days before the animal is experimentally infected with tubercle bacilli. Even then the development of the tuberculous process is only retarded and not prevented. It is not surprising, therefore, to find little encouragement from the few reports that have been made on the use of these chemicals in patients with pulmonary tuberculosis.

Nayer and Steinbach²⁰ report on 8 patients with extensive bilateral pulmonary tuberculosis who were given sulfanilamide from ten to seventy-one days with no apparent effect on the disease. Freilich, Coe and Wien²¹ treated 35 patients with moderately or far-advanced tuberculosis over a period of ten to fifteen weeks with sulfanilamide. The drug was given by mouth in 10-gr doses three times a day, and was gradually increased to 20 gr three times a day over a period of one month and kept at this level for the following six to ten weeks. The authors concluded that sulfanilamide was of no apparent value in altering the course of patients with pulmonary tuberculosis.

Faniel et al²² gave sulfanilamide to several patients, but reported that the treatment resulted in no appreciable modification of symptoms. They believe that the drug may act favorably on associated organisms without affecting the tubercle bacillus.

Allison and Myers²³ treated with sulfapyridine 7 patients having active pulmonary tuberculosis and 1 with acute generalized miliary tuberculosis. The patients were given the drug for a relatively short time, and no evidence was obtained that sulfapyridine influenced the course of the disease.

This group of over 50 cases is too small to justify final conclusions, but present evidence does not warrant the use of sulfanilamide and sulfapyridine in the treatment of pulmonary tuberculosis unless there is a definite secondary infection with organisms that are susceptible to the drugs.

PROGNOSIS OF PLEURISY WITH EFFUSION

Primary pleurisy with effusion has long been considered tuberculous unless otherwise proved, and figures reported early in the century are quoted to show that about 40 per cent of these cases later developed active pulmonary tuberculosis. These figures, however, are based on cases studied before x-rays had come into use, and it

is probable that a large proportion of them were not really primary pleurisy but pleurisy secondary to pulmonary tuberculosis, which a roentgenogram would have proved. With present x-ray facilities it is possible to determine with a high degree of accuracy whether pulmonary infection is present at the time the pleurisy develops, and only those cases with negative lung fields are now classed as primary pleurisy with effusion.

Study of the pleural fluid does not prove that all these cases are tuberculous, since the number of tubercle bacilli in the effusion may be very small. Guinea-pig inoculation has been positive in from 23 to 55 per cent of the cases in the various series reported. A recent survey of 58 cases studied at the Massachusetts General Hospital from 1916 through 1938 with no evidence of pulmonary lesions gave only 14 per cent positive findings on guinea-pig inoculation. This is a surprisingly low figure, but does not disprove a tuberculous etiology.

Trudeau²⁴ has recently reported a follow-up study of 54 cases of primary pleurisy with effusion that were followed from three to twenty-five years. Of this group only 4 patients developed evidence of pulmonary tuberculosis, and in 1 of these the lesion was doubtful. Trudeau concludes, "The prognosis of pleurisy with effusion with either negative, doubtful or extremely slight apical pulmonary findings by X-ray is excellent in patients receiving at least four months of sanatorium care, in fact, it is practically as good as the normal adult population in the same age group. This is an important factor in prognosis, but one must remember that all these cases had at least four months of rest treatment."

ETIOLOGY OF SPONTANEOUS PNEUMOTHORAX

In the past, spontaneous pneumothorax, like pleurisy with effusion has been considered tuberculous. Studies published during the last ten years, however, have all pointed to the nontuberculous etiology of this condition when it develops in a previously healthy person. The subject has been carefully summarized by Perry²⁵ who shows that of the 250 published cases only 2 per cent of the patients later developed tuberculosis. He describes the currently accepted explanation of this condition as the rupture of an emphysematous bleb. This bleb forms as a result of congenital defect, fibrous valvular obliteration of the

smaller bronchi or localized emphysema. Thoracoscopic examination will often reveal the lesion on the surface of the lung. Perry concludes: "Rest in bed for one week should be sufficient to allow the perforation to heal. Sanatorium treatment is quite unnecessary." In his series the pneumothorax recurred in 44 per cent of cases, other authors report recurrences in as high as 20 per cent.

Ylvisaker, Kiessling and Kirkland²⁶ report 17 cases of spontaneous pneumothorax among employees of a large business organization. In none of these could tuberculosis be proved, and of 13 cases tested with tuberculin 5 were negative.

1101 Beacon Street.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26201

PRESENTATION OF CASE

A sixty-six-year-old white woman was admitted to the hospital complaining of indigestion for a period of twelve years.

About twelve years before admission, following the death of her husband, the patient began having vague digestive symptoms characterized by anorexia, abdominal distention and "gas." These complaints persisted until about five years before entry when they became worse. X-ray studies at that time revealed a "high cecum, irritable colon and gallstones." Her stools became rather "shredded" in appearance and light in color, but she was otherwise well and lost no weight until one and a half years before admission, when she developed a vague dragging distress localized in the right lower quadrant of the abdomen and aggravated by the upright position. She also noticed that the ingestion of "rough" food increased these symptoms, and that gas seemed to be constantly moving around in the bowels. At that time roentgenograms of the abdomen showed "old tuberculous disease of the cecum." She was placed on a low-roughage, low-residue diet, and the symptoms improved but did not abate entirely. She then developed a severe case of "shingles" over the right thorax, with fever and a weight loss of a few pounds, from which she recovered uneventfully. About six months before entry the patient felt weak and her blood was found to be "low"; vitamin B complex with iron (Elixir Feosol) was prescribed. The blood did not respond to treatment, and she continued to feel weak. She became anorexic and lost weight, and developed pain in the right lower quadrant.

X-ray studies of the chest in an outside hospital showed "no parenchymal tuberculous infiltrative change." A gastrointestinal series was negative, except that the colon was hypermobile and there was delayed emptying time in the terminal ileum, one of the folds of which lay in the right iliac fossa and was moderately dilated. The cecum remained high, as previously noted, and between the cecal end and dilated fold there was an area of narrowing. Some external pressure changes were evident against the other coils of ileum, caused by rather marked thickening of the wall of

the terminal ileum or surrounding inflammatory change, possibly involving either the omentum or the surrounding lymph nodes. A barium enema was negative except for the extension of a slight amount of barium through the ileocecal valve into the narrowed terminal ileum. The colon was well emptied after evacuation. The stools remained "normal", no constipation, melena or other symptoms were noted.

Thirty-four years before admission she had undergone an appendectomy.

Physical examination revealed a fairly well developed and nourished woman who showed evidence of recent weight loss but did not appear sick. The examination was negative except for the presence of a firm, irregular, non-tender fixed mass, measuring about 8 by 11 cm., located in the right lower quadrant of the abdomen. The blood pressure was 112 systolic, 70 diastolic.

The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 3,900,000 and a white-cell count of 15,200. The serum nonprotein nitrogen, chlorides and protein were normal. An electrocardiogram was normal.

The patient was transfused, and on the eighth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR: Were the x-ray films taken here or outside?

DR. AUBREY O. HAMPTON: They were done outside, but we have copies. I do not agree with the interpretation. This, which was interpreted as cecum, is not the cecum. It really lies here, and most of the narrowing is in the ascending colon and cecum, both of which are diffusely involved by a similar process and are definitely shortened. It is true that the ileum is also involved and that the diameter of its lumen is reduced to almost a millimeter in the upper portion of the lesion, yet no real obstruction is present. One point in the ileum, which I should like to see much better, appears irregular, and there is a diverticulum-like pouch proximal to the constriction, as if the ileum had been working against obstruction over a long period of time.

DR. TAYLOR: You cannot say anything about the mucosal pattern from the film?

DR. HAMPTON: I think it is destroyed. The end of the defect is conical, rather than overhanging, as you might expect if that were malignant. She also had gallstones.

DR. TAYLOR: The x-ray diagnosis of tuberculous disease of the cecum was made one and a half years before admission. Are those films available?

DR. HAMPTON No

DR. TAYLOR Is it reasonable to make a flat footed diagnosis of cecal tuberculosis by x ray?

DR. HAMPTON There is a typical picture of ileocecal tuberculosis, but we do confuse it with ileitis.

DR. TAYLOR We have here, not to be elaborate about it, a longstanding history of gastrointestinal disturbance, the symptomatology of which is accounted for by what was found, namely an obstructive lesion involving the ascending colon in the region of the ileocecal valve and a large fixed mass. The problem is simply to decide what that mass was.

One should consider the possibility of foreign bodies following laparotomy, but the appendectomy was done some thirty four years before, and it seems to me that she would not have been likely to have anything starting as a sequela of that. We have seen inflammations due to perforation of the terminal bowel by foreign bodies. Tooth picks and porcupine quills will sometimes give rise to inflammatory masses in this region, but the conspicuous thing about the course is that except for the white count there was nothing to suggest an inflammatory process. In fact, we have to go at this with very little help except that there is some thing here by x-ray that there is a palpable mass and that is all. The laboratory studies do not contribute very much. No blood was noted in the stool examinations. There was a slight anemia—3,900,000. There are inflammations which would not have to show acute leukocytosis, such as tuberculosis and actinomycosis, but I do not see that we have anything except previous x-ray studies which would justify us in assuming that we are dealing with tuberculosis or actinomycosis. Ileitis is not at all common in elderly people, and with a twelve year history this patient should have had more overt manifestations of an inflammatory process, if ileitis had been present. One cannot rule it out, nor can one say that this is not tuberculosis, but both seem to me definitely unlikely. The chest plates showed no evidence of tuberculosis.

We then come to neoplasms, and against neoplasm is the long duration of the history and the relatively good state of health that she was in at the time of admission to the hospital. Carcinoma could not have endured so long. You can conceive of its developing on a pre-existing lesion, the nature of which I am unable to suggest. The same applies to lymphoblastoma. I had considered that we might be dealing in this case with a carcinoid on the ground that these tumors are essentially benign and may be present for a long

time without seriously impairing the patient's general condition. However, I do not see how we can say, on the strength of the material we have here, whether we are dealing with tuberculosis or with carcinoid. I am inclined to believe we are not dealing with a malignant neoplasm or a type of inflammatory change other than tuberculosis. Ulcerative colitis is a possibility, but there is nothing in the history to suggest the diagnosis. This lesion involves the terminal ileum and a restricted, localized area in the cecum. My first diagnosis is carcinoid, and my second, tuberculosis of the cecum.

DR. CLAUDE E. WELCH I can add but little. We were very much puzzled. As a matter of fact, we did not have Dr. Hampton's interpretation of the x-ray film, which might have some what changed our diagnosis. We thought we were probably dealing with a polyp of the cecum. The large size of the mass with no blood in the stools led to that diagnosis. She went through a two-stage resection without any difficulty.

CLINICAL DIAGNOSIS

Polyp of cecum

DR. TAYLOR'S DIAGNOSIS

Carcinoid

ANATOMICAL DIAGNOSIS

Tuberculosis of ileum, cecum and ascending colon.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY The diagnosis proved to be tuberculosis. The entire cecum and ascending colon were markedly shrunken, contracted in to a few centimeters, as you see in the x-ray plate according to Dr. Hampton's interpretation. There were several ulcerations, but the major part of the process could be fairly classified as hyperplastic. We found one ulcer 7 mm in diameter and several minute tubercles in the ileum, but the major process was in the cecum.

DR. WILLIAM B. BREED Dr. Hampton, would you be willing to make a definite diagnosis of tuberculosis on that film?

DR. HAMPTON Yes.

CASE 26202

PRESENTATION OF CASE

A thirty year-old man was first seen by his physician when he complained of fatigue and of not having felt well for a couple of months. He gave a history of never having had anything to eat ex

cept milk and dry cereals, and on rare occasions a leaf of lettuce or a banana. The cereal had to be obtained from individual boxes, and the milk from a certain dairy. He was accustomed to drinking three quarts of milk a day and said that he took this in much the same manner as he put gasoline into his automobile—in order to make it go. He was unable to eat a meal with the rest of the family because the sight and smell of other food disturbed him. His mother had found when he was a baby that she was unable to introduce beef juice into his bottle of milk, or to give him any food other than plain milk. She had consulted various physicians during his infancy and childhood with reference to his diet, but was told that he would probably outgrow his distaste for food. While he raised chickens as a livelihood he had never tasted chicken meat and, until entering the local hospital, had never tasted the juice of an orange.

While a good businessman he was eccentric as to habits, having had no association with girls or young women and very few close friends among the young men of his acquaintance.

On examination his general appearance was poor. His pasty facies suggested nephritis, but nothing else unusual was found. The systolic blood pressure was recorded as 115.

Because of his general condition he entered a local hospital. While there the nurses were unable to persuade him to take any food but milk from a particular dairy, except that on occasions he took small amounts of creamed vegetables and orange juice. He was also given brewers' yeast and Chlorosalsterol in an attempt to increase his vitamin intake.

Examination of the blood showed a red-cell count of 3,420,000 with 82 per cent hemoglobin, and a white-cell count of 14,000 with 70 per cent polymorphonuclears, 20 per cent lymphocytes, 6 per cent monocytes and 4 per cent eosinophils. The platelets were normal. There was some polychromatophilia and variation in the size and shape of the red cells. The nonprotein nitrogen was 300 mg per 100 cc, but the technician reported the result as approximate, due to cloudiness of the solution. The blood sugar was 166 mg per 100 cc. A renal function showed no phthalein excretion. The blood Hinton test was negative. The urine showed a specific gravity of from 1.009 to 1.004, it contained a large amount of albumin, and nothing in the sediment except an occasional hyaline cast.

X-ray examination of the stomach revealed this organ to be of normal size, outline and position, with some spasm at the pylorus. A barium enema

showed a hypertonic colon, which was interpreted as being due to a simple colitis. The Graham test was negative. The kidneys were reported as normal in size, shape and position, with no evidence of urinary calculi. No evidence of abnormality of the heart or lungs was noted in x-ray films of the chest.

While in the hospital he suddenly developed complete prolapse of the rectum, which was successfully treated by painstaking care. After being in the hospital twenty-two days he was discharged home, in the care of a very competent nurse, because of more or less dissatisfaction at being away from home. There he developed a cough, which was not troublesome until the last three or four days of life, when opiates were required for its control. There was very little sputum. Another outstanding symptom was increasing difficulty in voiding urine. He required six to eight minutes to start the stream, which would then voluntarily stop, and the same process had to be repeated each time he voided. The daily fluid intake averaged 2250 cc, and the urinary output ranged from 600 to 1200 cc. The daily intake of milk varied from 360 to 720 cc, the highest being 930 cc. The milk was unpasteurized and obtained from a Guernsey herd, the cows being fed, the year round, with Eastern States balanced ration containing 20 per cent of protein, together with green pasturage in the summer and hay, ensilage and carrots during the winter. This source of supply had been used for eight years, and a similar one had been used for the twelve years previous. There was an intake of from 120 to 360 cc of orange juice a day, one or two eggs were ingested as egg-nogs, and very small quantities of cereal such as oatmeal or cream of wheat, small quantities of macaroni, lettuce, carrots, celery soup and a few crackers were included in the daily menu. He was also given 30 to 90 cc of olive oil, yeast tablets, Digalin for his heart, and Sodium Amytal as a base sedative for restlessness. The cough was aided in the beginning by syrup of hydriodic acid, but later on required codein.

Physical examination on the day before death showed a well-developed and well-nourished man lying in bed. He was oriented and talked freely. His appearance was that of a patient with chronic nephritis, owing to pastiness of the face and puffiness about the eyes. The pupils were normal, the sclerae were pale, and the fundi showed nothing except pallor. The breath was normal, and he was breathing quietly. The tongue was coated, the teeth were in good condition, the mucous membranes were pale. He had small

buried tonsils. There were no enlarged lymph nodes. The chest was symmetrical and moved normally on respiration, the only abnormal finding being slight dullness at the right base, with moist rales. The apex of the heart was not palpable, but the left border of dullness was made out just outside the nipple line. The rhythm was regular, the rate 140. The sounds were of poor quality. Gallop rhythm was present. The blood pressure was 135 systolic, 65 diastolic. There was no evidence of sclerosis of the peripheral arteries. The abdomen was moderately distended, and because of this and the thickness of the abdominal wall, palpitation was unsatisfactory, however, there were no apparent masses or palpable viscera. The penis and both testicles were distinctly small in size. The knee jerks were normal, and there was no edema of the legs or feet.

The urine specimen obtained at the completion of the physical examination was less than 30 cc. in volume, it was cloudy, contained a large amount of albumin and showed a negative sediment. The blood smear showed the following differential polymorphonuclears 89 per cent, lymphocytes 6 per cent, basophils 1 per cent and large monocytes 4 per cent. The red cells showed some variation in size, there was surprisingly little achromia. The platelets appeared normal.

Because of the serious state of the patient and the difficulty in feeding, the suggestion was made that the patient be transferred back to the hospital for tube feedings of a solution of milk, cream sugar, eggs and orange juice sufficient to make up about 2500 calories. He was transferred to the hospital on the following day, but while preparations were being made for treatment the patient suddenly developed what appeared to be a severe attack of pulmonary edema, and died about an hour thereafter.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD J. CLARK. We are faced at the onset with the picture of a "peculiar individual," showing many of the earmarks of a psychopathic personality. For thirty years he had lived on three quarts of milk a day plus some dry cereals. Our immediate thought is that he may have been suffering from a deficiency disease. However, if he had taken three quarts of raw milk a day, he should have received adequate amounts of vitamins, protein and minerals with the exception of iron. He did lack the normal amount of intestinal bulk and roughage.

His primary complaint was one of fatigue, with no localizing systemic complaints. The physical examination was negative except for a nephritic facies.

The laboratory findings are somewhat surprising. He had a quite normal hemoglobin—82 per cent. The one recorded red-cell count was 3,420,000, indicating a rather high color index. The differential and smear were not suggestive of pernicious anemia. The nonprotein nitrogen of 300 mg per 100 cc. was strikingly high. Renal function by phthalein excretion was nil. The urine showed a fixed low specific gravity, with a large amount of albumin. The sediment was surprisingly negative. I presume that the blood-sugar level reported at 166 mg per 100 cc. was determined in a fasting specimen, it is somewhat high, although no glycosuria was noted. X-ray films of the kidneys showed normal size, shape and position. The gastrointestinal and chest films were essentially negative.

At the time of his first hospital discharge we are left only with quite definite clinical evidence of renal failure and laboratory evidence of uremia. There are several surprising factors in the situation. With a nonprotein nitrogen of 300 mg., a phthalein excretion of zero and a fixed specific gravity an elevated blood pressure is certainly to be expected with any ordinary type of nephritis. Also, more in the way of casts and cells in the sediment might be expected. It would be helpful to know something about the serum protein and sodium chloride, but this information is not given. There is no evidence for any specific type of pre renal azotemia. The normal appearing kidneys by x-ray tend to rule out congenital cystic kidneys, hydronephrosis and the like, as does the rather negative sediment. There is no past history given to indicate the onset of any acute nephritis. At the moment I am left with a diagnosis of renal failure, type uncertain.

After his return home he developed trouble in voiding urine. There is no report of a rectal examination and we know nothing about the prostate. In view of a urine sediment later that was still negative, it seems most unlikely that there was any growth or other factor causing an organic urinary obstruction. From the evidence at hand there is no proof of a cord lesion to account for this. I can only attribute this symptom to his state of general weakness.

It is stated that he also developed a cough. In view of subsequent events I should judge that this was coming from an early pulmonary congestion due to circulatory failure. A recent chest plate was negative, and we are not told that he had fever.

At the time of the examination on the day before death, he still showed a nephritic facies, but surprisingly we are told that he was well nourished. The fundi were negative. He apparently did not

have a uremic odor to his breath. He had some congestion at the right lung base. The heart showed some signs of weakening, with slight enlargement to the left and a rapid rate with sounds of poor quality and gallop rhythm. The blood pressure was relatively normal. There was no arteriosclerosis. The genitalia were small, being one bit of evidence for a possible endocrine dyscrasia, but there was nothing else to tie up with this. There was a large amount of albumin in the urine, the specific gravity is not given, and the sediment was negative.

The following day the patient developed acute pulmonary edema and died of what would seem to be acute congestive heart failure. Over the course of observation he had shown evidence of progressive myocardial weakness. There is no evidence for rheumatic, congenital or hypertensive heart disease. There is no arteriosclerosis or evidence for coronary disease. Hence, the heart failure must have been myocardial. With a state of relative malnutrition, did he have a beri-beri heart? On his original three quarts of milk a day, he should have had an adequate intake of vitamin B. Later, after discharge from the hospital, 360 to 720 cc of milk would not give an adequate intake, but when supplemented by yeast,—we are not told how much,—it would seem probable that the vitamin B intake was sufficient to prevent beri-beri. I can make no definite cardiac diagnosis, but believe that an enlarged heart will be found, with myocardial degeneration, and consequent pulmonary congestion.

I believe that the postmortem will show a chronic renal lesion which was most likely the primary cause of his death. It will probably be of the chronic glomerular type, but I am disturbed by the lack of hypertension and other vascular changes. The peculiarities of diet, with possible iron lack at first and more general deficiency later, probably contributed to his general weakness, but I suspect they were not the primary cause of his final illness.

There is very likely an unseen "catch" in this case to explain the low blood pressure and, possibly, the cause of the pre-renal azotemia. The postmortem findings should be most interesting.

CLINICAL DIAGNOSES

Food phobia
Chronic nephritis?

DR CLARK'S DIAGNOSES

Psychopathic personality
Chronic glomerular nephritis
Uremia

Myocardial hypertrophy and degeneration (beri-beri heart?)

Pulmonary congestion

Inanition from dietary inadequacy

ANATOMIC DIAGNOSES

Chronic glomerular nephritis

Acute pulmonary edema

Parathyroid hyperplasia, secondary

Cardiac hypertrophy, slight

Edema, slight, generalized

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY. This is the type of case in which the differential diagnosis must be begun all over again when the facts of the post mortem examination become available. The latter are easily stated. The kidneys were extremely small, with a combined weight of only 75 gm., and the right kidney was twice the size of the left. Neither the pelves nor the ureters were dilated or showed any evidences of infection, and the prostate was normal in size. The heart was slightly hypertrophied, weighing 375 gm., and there was minimal atheroma of the coronary arteries. The lungs showed massive pulmonary edema. The liver was somewhat inexplicably large, weighing 2360 gm and showing neither passive congestion nor fatty infiltration. Next to the kidneys the most striking organs in the body were the parathyroid glands, all four of which were markedly enlarged and which together weighed 860 mg. Microscopic examination of the parathyroid glands showed marked hyperplasia of the so-called "secondary type," which is characteristically found in patients with very long standing renal insufficiency. One could wish that certain other laboratory examinations had been performed, but we can predict confidently that the serum calcium would have been found somewhat low, the serum phosphorus considerably elevated and in all probability the serum phosphatase also increased. Microscopic examination of sections from the bones shows slight but definite evidence of parathyroid activity, with both bone destruction and bone formation increased in amount and a few minute areas of fibrous replacement of the marrow. The process, however, was probably not extensive enough to have been visualized by x-ray examination. I know of no way in which to recognize a beri-beri heart post mortem. So I must leave that question unsettled. I can only say that there was no morphological evidence of myocardial edema.

The crux of the diagnosis rests in the attempt to identify the underlying renal pathology. A

few years ago the lesions in the kidneys would almost unquestionably have been diagnosed without much hesitation as being due to chronic glomerular nephritis. In the interval Longcope and Winklerwerder¹ and Weiss and Parker² have called our attention to the frequency of healed pyelonephritis. Longcope particularly emphasized the frequency with which it was responsible for very prolonged renal insufficiency and noticed that certain of the cases never developed hypertension. Parker and Weiss, in contrast, have emphasized the role of chronic pyelonephritis in producing a clinical picture indistinguishable from that of malignant hypertension. The latter authors have described in detail the criteria for the histologic recognition of this lesion. Factors such as a deformity of the pelvis, inflammatory infiltration beneath the pelvic epithelium, marked inflammatory infiltration throughout the renal parenchyma, focal wedge shaped areas of scarring, disproportionate destruction of tubules as compared with that of glomeruli, periglomerular fibrosis and the formation within the tubules of a peculiar type of dense hyaline casts suggesting the colloid of the thyroid gland are all points in favor of a chronic pyelonephritis. I have tried hard to fit this case into that category, since its clinical course is so atypical for that of a glomeru-

lar nephritis. However, I do not seem to be able to do so. The difference in size of the two kidneys and a very diffuse inflammatory infiltration throughout the parenchyma seem to be points suggestive of a pyelonephritis. In contrast, however, there was no pelvic deformity on either side, and no inflammatory infiltration immediately beneath the pelvic epithelium. The glomeruli seemed to be more extensively involved than were the tubules, and although many casts were present, only a few of them were convincingly of the colloid type. The glomeruli themselves, moreover, although free from active inflammatory changes, showed unusual numbers of capsular adhesions, and even in the best-preserved areas some degree of fibrosis was present in almost every glomerular tuft. I feel forced, therefore, to make a diagnosis of chronic glomerular nephritis rather than one of pyelonephritis, despite the very unusual clinical course. It is interesting, in view of the absence of hypertension, that the arteries and arterioles within the kidneys showed only slight intimal fibrosis and no necrotizing arteriolitis.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston, Massachusetts.

LAST CALL

THE annual meeting of the Massachusetts Medical Society on Tuesday and Wednesday, May 21 and 22, deserves a record attendance because of the comprehensiveness and the excellent co-ordination of the program. The latest views on a larger number of medical subjects will be presented by specialists in each field. Because of careful planning this will be accomplished in two days. There is no competition in subjects, except at the round-table meetings and luncheons, owing to the abandonment of the scheme of presentation of papers by sections.

The notable list of guest speakers appearing on the program offers a unique opportunity of hearing authoritative opinions on certain new developments and controversial questions. Surgeon-General Thomas Parran will discuss syphilis, Dr

Perrin H. Long, sulfanilamide and allied compounds, Dr Francis G. Blake, pneumonia, and Dr Reed Nesbit, the various methods of treating prostatic obstruction. Dr Esmond R. Long and Dr Edith Lincoln will describe the present views on the pathogenesis and management of adult and childhood tuberculosis. Dr Wilson G. Smilie, a former member of the Society, will consider various aspects of the common cold. Equally qualified men in their fields who are members of the Society will discuss many other important topics, such as breast tumors, pulmonary infections, toxic manifestations of important drugs, urinary-tract infections, streptococcal infections of the respiratory tract, gonorrheal arthritis, syphilis in many of its manifestations and so forth. In addition there are many interesting and instructive scientific and commercial exhibits.

It is unquestionably true that one will be well repaid for spending these two days at the Copley Plaza Hotel.

THE BOSTON MEDICAL LIBRARY A COMMUNITY INTEREST

THE annual report of the librarian of the Boston Medical Library for 1939, appearing in this issue of the *Journal*, again calls attention to the usefulness of this old institution in the community. Ten thousand persons used the library in the course of the year, an unusually large number when one thinks of the specialized nature of the collection and the other opportunities to read and look up references in the medical literature. Although many hospitals and the medical schools in Boston and its vicinity have working libraries, it would seem that the demand for a large, central library, with resources greater than those of other groups, is ever-present. That this demand is met by the Boston Medical Library appears clear from the report.

The ten thousand persons using the library in a year consisted of members, visiting scholars, students from many schools and the public. The library must, by reason of the article of its incorporation and because of its obligations to other institutions, be open to the public, although no

support, other than tax-exemption, is obtained from public funds. To the layman, therefore, the library is a source of medical information. With the widening interest of the public in medical matters, the importance of this provision becomes more and more evident, and although the collection is designed primarily for doctors and medical students, the use of it by the public is wisely not discouraged.

The library, moreover, maintains a large file of current medical periodicals, many of which are not available elsewhere in Boston, an unusual number of bound magazines, going back to the earliest days of medical literature, the current text books and monographs, an unrivaled collection of incunabula, and thousands of medical dissertations, general historical material and Americana. Built up through years of selective acquisition, no library in the country holds a finer or more useful collection based on the needs of the community that it serves.

That the purposes and aims of the Boston Medical Library are recognized is well attested by the growing membership and the increased use of the material on its shelves. The library thus maintains its position, as it has in the past, as an integral part of the cultural and scientific life of Boston in the fields of medical research and of the advancement of medical knowledge.

MEDICAL EPONYM

BROCA'S AREA

At the fortieth session of the Société d'anthropologie de Paris, April 18, 1861, Paul Broca (1824-1880), assistant professor of the Paris Faculty of Medicine, made a communication, a summary of which was published in the *Bulletin de la Société d'anthropologie de Paris* (2: 235-238 1861), under the following title: "Perte de la parole, ramolissement chronique et destruction partielle du lobe antérieur gauche du cerveau [Loss of speech chronic softening and partial destruction of the left anterior lobe of the brain]. A portion of the translation follows:

M. Broca at this session, demonstrated the brain of a man fifty-one years of age who had died on his service at the hospital at Bicêtre and who for twenty-one years, had lost the power of speech. The patient

died April 17, 1861. At the autopsy, the dura mater was found to be thickened. The frontal lobe of the left hemisphere was softened throughout the greater part of its extent. The softening had extended posteriorly as far as the ascending convolution of the parietal lobe and downward as far as the marginal convolution of the temporosphenoidal lobe but it was obvious at first sight that the principal seat and origin of the softening had been the medial part of the frontal lobe of the left hemisphere. It seems reasonable to believe that in this actual case the lesion of the frontal lobe was the cause of the loss of speech.

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., Secretary
330 Dartmouth Street
Boston

PYELITIS OF PREGNANCY

Mrs. M. E., a thirty year-old para III, was admitted to the hospital on September 3, 1930, in the fifth month of her pregnancy, complaining of right-sided pain, fever, general malaise, dysuria and nocturia.

The family history was essentially negative. The patient's history included three tonsillectomies, frequent cervical adenopathy and several previous cystoscopies. She had had a history of chronic pyelitis for three years. The two previous pregnancies had been normal. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted five days. The last period was April 14, making the expected date of confinement January 21, 1931.

Physical examination showed a well-developed and well-nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. There was definite tenderness over the right kidney. The uterus was enlarged consistent with the period of amenorrhea. Examination of the urine showed large numbers of white blood cells in clumps, no red blood cells and no casts. A culture showed *Bacillus coli*. The temperature varied from normal to 103°F for the first three days, then remained normal.

The treatment was at first supportive and symptomatic, oral urinary antiseptics being given. Then,

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

on September 5, two days after admission, a cystoscopy was performed and the right infected renal pelvis was irrigated with boric acid solution, followed by the instillation of 10 cc. of 2 per cent Mercurochrome. The ureteral catheter was left in place for twenty-four hours. On September 10 another cystoscopy was done, this time with lavage of the left renal pelvis, followed by the instillation of 12 cc of 2 per cent mercurochrome. The acute symptoms had subsided by September 13, and the patient was discharged.

On September 24, the patient was readmitted to the hospital complaining of right-sided pain. There was no fever or other symptoms. The urinary findings were the same. A cystoscopy was done on September 27, and the right renal pelvis was irrigated with boric acid solution and 10 cc of 2 per cent Mercurochrome was instilled. She was discharged September 28.

The patient was followed in the office throughout the remainder of her pregnancy, which passed without recurrence of the pyelitis. She was admitted to the hospital in labor on January 22, 1931, and delivered uneventfully. The urine still showed many white blood cells in clumps, but the temperature remained normal throughout her hospital stay. She was discharged on the seventeenth postpartum day.

Comment. This case illustrates the more modern treatment of pyelitis. For many years the treatment was entirely constitutional and supportive, abetted by urinary disinfectants. Catheterizing ureters, culturing the urine and washing out the pelvis of the kidneys illustrate a recent phase in the intelligent treatment of pyelitis. The culture in this case showed *B. coli*. Many cases that have been subjected to ureteral catheterization and renal lavage have shown marked improvement. Some of these cases, however, go on to definite kidney damage—either an abscessed kidney requiring nephrotomy or a true surgical kidney requiring nephrectomy. The subsequent history of this patient is unknown, but the washing out of the renal pelvis was apparently curative.

ROUND-TABLE MEETINGS AND LUNCHEONS

The following are the completed programs of four of the round-table meetings and luncheons to be held from noon until 2:00 p.m. on Tuesday, May 21, at the annual meeting of the Massachusetts Medical Society. The program of the fifth

meeting—that of the Section of Obstetrics and Gynecology—was published in the May 9 issue of the *Journal*.

Section of Dermatology and Syphilology

STATE SALON, COPLEY PLAZA HOTEL

Chairman Dr C G Lane, Boston.
Secretary Dr J G Downing, Boston

Subject *Manifestations of Skin Disease on Extremities Diseases Usually Localized to the Hands* Dr C G Lane, Boston

Diseases Usually Localized to the Feet Dr W P Boardman, Boston

Diseases Localized to the Lower Legs Dr J G Downing, Boston

Diseases with Manifestations on Extremities as Part of the General Picture Dr G M Crawford, Boston.

Fungous Diseases of the Extremities Dr J H Swartz, Boston

A Study of the Hydrogen Ion Concentration of the Skin of the Hands and Arms I H. Blank, Boston

Surgical Considerations of Dermatoses of the Hands Dr T W Harmer, Boston

Section of Medicine

PRESIDENT'S ROOM, UNIVERSITY CLUB

Chairman Dr C M Jones, Boston
Secretary Dr E C Miller, Worcester

Subject *Toxic Manifestations of Important Drugs.* Speakers Drs Samuel A Levine, C S Keeler, C L. Short, Alexander Marble and C M. Jones, Boston. Followed by a general discussion.

Section of Pediatrics

BALLROOM, WESTMINSTER HOTEL

Chairman Dr C F McKhann, Boston.
Secretary Dr J M Baty, Boston

Subject *Allergy in Childhood* Speakers Drs. L W Hill, H N Pratt and E. A. Brown, Boston.

Section of Surgery

CRYSTAL ROOM, WESTMINSTER HOTEL

Chairman Dr R. H. Smithwick, Boston
Secretary Dr B C Wheeler, Worcester

Subject *Vitamins and Surgery* Speakers Drs. Cornelius P Rhoads, New York City, and C. C. Lund and A W Allen, Boston. Followed by a general discussion.

All those who are planning to attend the round table luncheons and meetings should get their tickets at the Registration Desk as early as possible on Tuesday morning in order that proper accommodations can be provided. Tickets for all luncheons are \$1.00.

THE SCHOOL CHILD*

When a child begins to go to school he enters on a phase of his life quite different in many respects from the years which have gone before. Until this time his activities have been associated almost entirely with the home, and through the home have come the influences guiding his physical and mental growth and development. From his first day at school and increasingly as he grows older he is surrounded by a new physical environment and is subjected to the influence of teachers and other individuals not connected with his home. His life becomes bound up with the educational system. This change requires many adjustments, some of which must be made at once and others more gradually as he progresses from grade to grade. I cannot discuss at this time the educational aspects of the school child but must confine myself to the effect which the new contacts have on his health.

The basic health needs of the child are the same at every age period, but some of them call for special emphasis during the school years. The school should offer to the child every opportunity to attain the optimum condition of health and should protect him so far as possible from the hazards which act unfavorably on health. Let us consider a few of the situations in relation to school life which have a direct bearing on health.

In order to grow and develop normally every child needs the proper food. The school may make its contribution in this particular by supplying a well-balanced meal for those children who do not go home for lunch. The preparation and serving of the lunch may also furnish an opportunity to instruct the child in food values and in desirable food habits. It may supply a practical demonstration of the formal instruction in the school-room. How many of you who are listening know about the lunch which your child eats at school? If he buys the food, does he spend his money for sweets and cold drinks or for nourishing food and milk? What is the choice offered him? Is someone trying to make a profit on the school lunch or is the food supplied at cost and selected for its food value? Parents might well interest themselves in these matters.

Every child should be given good care for his own body. In the early years this is done for him but, as he advances in age, he must learn to assume this responsibility for himself. The school may render real assistance, not only through specific instruction but through practical demonstration. Physical education and athletic departments have been established for this purpose. Are they being conducted in your child's school so that every pupil is learning the proper use of his body and the easy co-ordination of his muscles? Is the sports program conceived for the benefit of the whole school group or for the potentially successful athlete? Is proper consideration being given to the age of your child, or is his physical activity too advanced for his bodily development? Do the skills which he is acquiring have any relation to future values, and do they meet present needs? These are questions which parents might investigate.

The alternation of work and relaxation is essential to a healthy life. Do you know what your child's daily school schedule is? If his progress in studies is satisfactory you probably have not looked into the matter. If he is having a hard time with his lessons, do you know whether he is being pushed too hard with work at school or is spending too much time in other interests? I have said

be" in all references to the school child merely for convenience of expression, but the questions raised are just as pertinent to the girl as to the boy. Her school schedule needs an equal and intelligent scrutiny. She has the same academic requirements in studies, and she needs the same relaxation in her recreational program.

Right here one ought to ask what the child does out of school hours. Attention has been called to the fact that a large part of the child's time is spent under the influence and direction of the school but the rest of the time is, theoretically at least, under the control of the parents. I say "theoretically" because in many instances the child is left to his or her own devices and the result may or may not be satisfactory from the point of view of health. We must remember that the child's life is a unit work and play must each have its proper place in the whole day's program and neither carried on to excess. Outside activities—parties, extra lessons, additional exercises—need to be considered in relation to the school schedule and used to supplement that schedule not to add a further load in a field which may be overburdened already. These matters are up to the parents. When one studies the daily routine of some children one is impressed with the fact that they have no free time—every hour of the day is filled with an engagement, so carefully planned that an appointment system is necessary. Some of these activities are desirable and furnish pleasure and relaxation to the child others however are unnecessary and should be eliminated. Every child should have some time each day when he does what he wants to do without the pressure of outside domination. This can be accomplished only through thoughtful planning. The school must co-operate by not requiring homework for children under twelve years of age and by expecting only a reasonable amount of homework from older children.

Parents may make another contribution to the child's health by planning the right kind of week ends. Monday morning should find the child rested and anxious for the school week yet the reverse is often the case. Every school principal will tell you that many children start the week more weary than they were on Friday night. Is your family week end planned for the benefit of the children or the adults? This is worth careful consideration.

Parents must assume full responsibility for one aspect of the child's life, that of ensuring an adequate amount of rest and sleep. There is some variation in the sleep requirements of different children but it is safe to say that no child is in danger of getting too much sleep. The fact is that few children get enough sleep. Fatigue is an important factor in causing ill health, and fatigue in children dependent on lack of sleep is the background on which many troubles of the body and mind may develop. This is the time of year particularly when children are most likely to show the effects of too strenuous a program and too little rest. The short days with a relatively small amount of sunlight the confinement indoors during most of the day the pressure of competitive school life, the piling up of extra scheduled activities, all combine to produce fatigue and nervous tension. It is essential that sleep be adequate if health is to be maintained.

I have spoken thus far almost entirely of bodily health but healthy minds are important also. One sometimes forgets how many new or different situations are presented to the child during school life. He must learn to recognize a constituted authority other than that of his parents, to act in harmony with a group whether in work or play to recognize an ultimate goal and be will

*Green Light to Health broadcast given by Dr. Richard M. Smith, on February 24, 1940, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

ing to work hard to attain it, to subordinate immediate pleasure for a future, more enduring satisfaction. In short, he must learn to live in a world of people—to become a part of that world and to make his contribution to its well-being. If the training by his parents during the preschool years has been good, these adjustments come naturally and without conflict, but if the early training has been faulty, school life may present many difficulties. The child who is doing badly in school may be having too hard lessons or too many outside activities, as has been suggested, but the explanation is quite as likely to be found in some emotional disturbance—he may feel himself out of place and misunderstood. The co-operation of the parents with the school is essential for a happy solution. The child who learns to live well with his school companions is started on an orderly and a useful life. The child who leaves school maladjusted to his environment begins life in the world with a handicap to be overcome, often with great difficulty.

* * *

Q Dr Smith, you have not said anything about the diseases which children often catch at school.

A. I am glad you mentioned that point. Children often do get diseases, especially colds, from contact with other children at school. Parents can be of real assistance in solving this problem. If every mother would be scrupulously conscientious about keeping her own child away from school when he had a cold, the source of infection would be eliminated. It is a strange observation that many mothers who are critical of a school situation where their own children are exposed to a cold are careless about sending their children with colds to school. It does not seem to be appreciated that one's own child may give a cold as well as get one.

Q You spoke about the need for an adequate amount of sleep. Will you not say a little more about that subject.

A. Yes, I am glad to emphasize again the importance of rest and sleep. There are many temptations for the child to stay up late at night. Today the radio is perhaps the thing most often to blame, some programs, popular with the young child, come at an hour after he should be in bed and asleep. Some programs are so exciting that when they are finished sleep is impossible. I do not know of any way to meet this difficulty except to avoid these programs. But, if the mothers of the country acted together, something really constructive could be accomplished. Such united action is necessary, also, if the neighborhood bedtime is to be early enough for children to receive the hours of rest which they need.

Q Is it not difficult to consider the child's whole daily program when the responsibility for his time is partly that of the school and partly that of the parents?

A. No, it is not difficult, but it does take thoughtful consideration. It requires sympathetic co-operation. The parents must know what the child's program is, and the school must know the individual capacities of the child. Both parents and school authorities may have to make adjustments in preconceived ideas to meet the circumstances. Each needs the help of the other. The child is the important person to be considered. It is worth making the necessary effort to maintain and improve his health.

DEATHS

HEWITT—WILLIAM O. HEWITT, M.D., of Attleboro, died April 27. He was in his sixty-fourth year.

Dr Hewitt received his degree in 1900 from Harvard Medical School. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

O'BRIEN—WALTER J. L. O'BRIEN, M.D., of Jamaica Plain, died May 1. He was in his sixty-seventh year.

Born in South Boston, he attended Boston Latin School and Harvard University. He received his degree from Harvard Medical School in 1898, and served his internship at the Rotunda Hospital, Dublin.

Dr O'Brien was a fellow of the Massachusetts Medical Society and the American Medical Association and was a member of the West Roxbury Medical Society.

His widow and a cousin survive him.

PECK—MARTIN W. PECK, M.D., of Boston, died May 7. He was in his sixty-first year.

Born in Montpelier, Vermont, he attended Dartmouth College and received his degree from Harvard Medical School in 1915. For two years following his graduation he was assistant physician at Devereux Mansion, Marblehead, and from 1919 to 1921 was assistant physician at the Sheppard Pratt Hospital in Townsend, Maryland. He was resident physician at the Boston Psychopathic Hospital the following year, and chief of the outpatient department from 1922 to 1926. Dr Peck was instructor in psychiatry at the Harvard Medical School from 1923 to 1937 and assistant psychiatrist at the Massachusetts General Hospital.

Among his affiliations were memberships in the Massachusetts Medical Society, the American Medical Association, the American Psychoanalytic Association, the American Psychiatric Association and the New England Society of Psychiatry.

His widow survives him.

WRIGHT—WILLIAM F. WRIGHT, M.D., of Portsmouth, Rhode Island, died April 11. He was in his sixtieth year.

Born in Fall River, he received his degree from Baltimore Medical College in 1908. Dr Wright practiced in Fall River before moving to Portsmouth, Rhode Island, in 1930. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

MISCELLANY

INTESTINAL TUBERCULOSIS

Hippocrates noted that there is an association between pulmonary and intestinal tuberculosis. But even to the present day the exact relation of pulmonary to intestinal tuberculosis has remained obscure. Light is shed on the subject by correlating the clinical with the pathological findings, as was done at Sea View Hospital where more than 1000 cases of tuberculosis were autopsied. A summary of the article describing the study (Cullen, J. H. Intestinal Tuberculosis. A clinical pathological study. *Quart Bull Sea View Hosp* 5:143-160, 1940), together with brief comments, follows.

1. A study of 1043 autopsied cases of tuberculosis is presented with an incidence of 734 cases, or 70.4 per cent, of intestinal tuberculosis.

The study included all cases of tuberculosis, both pulmonary and extra pulmonary which were ascertained during a five-year period, 1934 to 1938.

2. Intestinal tuberculosis is less extensive and less frequent above the age of forty

The greatest number of cases occurred between the ages of twenty and thirty-four years—76 per cent in this age group showed intestinal involvement. When cases of intestinal tuberculosis are divided according to the extent of intestinal involvement, it is found that in the older age groups, intestinal tuberculosis, when present, tends to be less extensive. The lower incidence and extent of intestinal tuberculosis in the older age group have never been satisfactorily explained.

3. Intestinal tuberculosis is more extensive and frequent in women and in Negroes than in men and Whites.

In the material studied, there were about twice as many men as women, and among them the incidence of intestinal tuberculosis was 4.6 per cent in the women and 6.2 per cent in the men.
The incidence in Whites was 66.4 per cent; Negroes, 77.3 per cent.

4. Although caseous pneumonic tuberculosis is the type of pulmonary disease most frequently associated with intestinal tuberculosis the cases with acute miliary tuberculosis showed a surprisingly high incidence (63.8 per cent) of intestinal involvement.

Most workers believe that direct contact of the tubercle bacilli with the mucosa of the intestinal mucosa is the most important single factor in producing intestinal tuberculosis. A few believe that hematogenous dissemination is the chief method. With that in mind, the cases studied were divided according to the character of their pulmonary disease.

The high incidence in acute miliary tuberculosis seems to indicate that the hematogenous route of intestinal involvement is much commoner than is generally supposed. One is also led to suspect that the bacilli-taken up in the blood are often only modified in the extent and site of the intestinal ulcer and is not itself the cause of intestinal tuberculosis.

5. The incidence of caseous mesenteric lymph nodes and miliary foci in the liver and spleen increases with the severity of intestinal tuberculosis.

Caseous mesenteric lymph nodes were found in 43 per cent of the cases and miliary foci in the liver (49.4 per cent) and spleen (47.8 per cent) in intestinal tuberculosis. It is considered that only routine sections were taken—more careful search would probably have yielded a higher incidence.

6. Intestinal tuberculosis is most frequent in the ileocecal region.

In this series of 734 cases of intestinal tuberculosis the ileum was involved in 652 and the cecum in 535. Extension of the tuberculous process is more frequently situated toward the stomach, which was involved in only 4 cases. The small intestine was involved alone more frequently than was the large intestine.

The character of the intestinal lesions varies just as in tuberculosis of other parts of the body. The earliest lesions are the lymphoid nodules of the submucosa, principally in Peyer's patches. The area of caseation finally involves the mucosa and ulceration results. The healing process consists of fibrosis of the specific tubercles followed by epithelial regeneration. The necrotic material sloughs out and the contraction of the fibrous tissue tends to approximate the edges of the ulcer. The unsloughed epithelial cells at the border of the ulcer creep in and finally cover the floor of the ulcer.

7. Perforation of a tuberculous ulcer occurred in 28, or 3.81 per cent, of the cases with intestinal tuberculosis. It occurred most frequently in the ileum.

Perforation caused a generalized peritonitis in 10 cases, a localized peritonitis in 16 cases. Three perforations were extraperitoneal. Two ulcers in the ileum penetrated into the pericolic tissues and once an ulcer in the cecum penetrated retroperitoneally. Perforation occurred most often in the ileum and least often in the appendix.

8. Generalized tuberculous peritonitis, except in those cases due to perforation of a tuberculous ulcer is not related to intestinal tuberculosis.

Tuberculous peritonitis not associated with intestinal tuberculosis, occurred in 52 cases.

9. The incidence and severity of intestinal tuberculosis are much less in those cases which have had pulmonary symptoms one to two years.

The frequency of intestinal tuberculosis is listed in the duration of the pulmonary disease. The highest incidence of intestinal tuberculosis occurs in cases with pulmonary symptoms of one year to twenty-three months' duration before death. As the duration of pulmonary symptoms increases the incidence and severity of intestinal tuberculosis decrease. Just why cases of long duration should not develop intestinal tuberculosis in spite of persistently positive sputum is not known.

10. The incidence and severity of intestinal tuberculosis are directly related to the positivity of the sputum.

The frequency and severity of intestinal tuberculosis were correlated with the degree of positivity of the sputum. Except for those cases which were positive on concentration only the incidence and extent of intestinal tuberculosis increase as the number of tubercle bacilli in the sputum increases. Cases that had a mean Gaffky count of VII X had an incidence of 1.83 per cent intestinal involvement. Cases that were negative on concentration had a incidence of 40.4 per cent.

11. The symptoms of intestinal tuberculosis are frequently misleading and are often present in cases with out any intestinal involvement.

Symptoms and signs may be bizarre, slight and easily overlooked. Symptoms became more frequent as the severity of intestinal involvement increased.

12. The diagnosis of intestinal tuberculosis based on roentgenograms was inaccurate in 29.2 per cent of the 113 cases studied roentgenographically and at postmortem.

Another writer found the intestinal x-ray unreliable in 52 per cent of his a series of 67 cases. The x-ray fails to substantiate many cases diagnosed as intestinal tuberculosis on x-ray. It is admitted that pseudo filling defects seen on x-ray may have been misinterpreted as evidence of organic disease, since fluoroscopy as recommended by Brown and Sampson was not done.

The other factor that accounts for some of the disagreement found between x-ray and autopsy is the fact that the x-ray criteria of tuberculosis of the ileum—distention, segmentation and stasis—are not so accurate as the criteria for diagnosis in the rectum and colon.

NOTES

Forty-four appointments to the teaching and research staff of the Harvard Medical School effective at the beginning of the next academic year were recently announced by the University as follows: Emanuel B. Schoenback, M.D. Harvard 37 now at Harvard Medical School instructor in bacteriology; Alan C. Batchelder, Ph.D. University of California 39, now at Johns Hopkins Hospital research fellow in physical chemistry; Maurice M. Tolman, M.D. Harvard 27 of Boston, assistant in dermatology; Edwin V. Hill, M.D. Tufts 39 now at Massachusetts Memorial Hospitals, research fellow in legal medicine; Charles H. Burnett, M.D. University of Colorado 37 now at Boston City Hospital assistant in medicine; John H. Dingle, M.D. Harvard 39 now at Children's Hospital, Boston assistant in medicine; Herman Erlanger, M.D. Washington University 37 now at University Hospital Ann Arbor Michigan, assistant in medicine; Robert S. Evans, M.D. Harvard University 38 now at Boston City Hospital assistant in medicine; William Parson, M.D. Columbia University 37 now at Massachusetts General Hospital, assistant in medicine; Conger Williams, M.D. McGill University 37 now at Massachusetts General Hospital, assistant in medicine; William P. Chapman, M.D. McGill University 38, now at Massachusetts General Hospital; Henry P. Walcott, Fellow in Clinical Medicine; Arthur M. Bassett, M.D. University of California 38 now at University of California Medical School, San Francisco, research fellow in medicine; Henry H. Brewster, M.D. Harvard University 38 now at Boston City Hospital research fellow in medicine; Joseph H. Burchenal, M.D. University of Pennsylvania 37 now at Boston City Hospital, research fellow in medicine; Richard V. Ebert, M.D. University of Chicago 37 now at Peter Bent Brigham Hospital, research fellow in medicine; Alfred F. Goggio, M.D. University of Toronto 38 now at St. Michael's Hospital Toronto, Canada, research fellow in medicine; Marlow B. Harrison, M.D. Harvard 36 of San Francisco, research fellow in medicine; Sibley W. Hoobler, M.D. Johns Hopkins 38 now at University Hospital Ann Arbor Michigan, research fellow in medicine; John W. Howard, M.D. University of Pennsylvania 36, now at Pondville Hospital, Wrentham, Massachusetts research

fellow in medicine, David A. Karnofsky, M.D. Stanford University '40, now at Stanford University Hospital, research fellow in medicine, Osler L. Peterson, M.D. University of Minnesota '39, now at University of Minnesota Hospitals, research fellow in medicine, James L. Whittenberger, M.D. University of Chicago '38, now at Department of Surgery, University of Chicago, research fellow in medicine, Daniel W. Badal, M.D. Western Reserve University '37, now at Boston Psychopathic Hospital, assistant in neurology, Richard B. Pippitt, M.D. Harvard '37, now at Massachusetts General Hospital, assistant in neurology, Lazarus Secunda, M.D. Columbia University '36, now at Boston Psychopathic Hospital, assistant in psychiatry, Robert H. Barker, M.D. Harvard University '34, of Boston, assistant in obstetrics, Otto E. Aufranc, M.D. Harvard '34, of Boston, assistant in orthopedic surgery, John A. Reidy, M.D. Harvard '34, of Boston, assistant in orthopedic surgery, Oscar S. Staples, M.D. Harvard '35, of Boston, assistant in orthopedic surgery, Charlotte L. Maddock, M.D. Boston University '29, now at Children's Hospital, Boston, research fellow in pediatrics, Donald L. E. Thurston, M.D. Vanderbilt University '37, now at Children's Hospital, Boston, assistant in pediatrics, Ernest M. Worden, M.D. University of Toronto '36, now at Children's Hospital, Boston, assistant in pediatrics, Walter R. MacLaren, M.D. Harvard '38, now at Massachusetts General Hospital, research fellow in pediatrics, Hudson Hoagland, Ph.D. Harvard '27, now at Department of Physiology, Clark University, research associate in physiology, Edward S. Lee, Jr., M.D. Meharry Medical College '37, now at Meharry Medical College, Nashville, Tennessee, research fellow in physiology, Hanns C. Schwyzer, M.D. University of Minnesota '39, of St. Paul, Minnesota, research fellow in physiology, James H. Wills, S.M. Medical College of Virginia '36, now at University of Rochester School of Medicine, research fellow in physiology, John R. Mote, M.D. Harvard '35, of Cambridge, Massachusetts, assistant in preventive medicine and epidemiology, Albert J. Sheldon, S.D. Johns Hopkins '37, now at Division of Public Health, University of North Carolina, Charles Follen Folsom, Fellow in Preventive Medicine, Dwight E. Harken, M.D. Harvard '36, of Osceola, Iowa, assistant in surgery, Stanley O. Hoerr, M.D. Harvard '36, now at Peter Bent Brigham Hospital, assistant in surgery, Robert R. White, M.D. University of Rochester '37, now at Peter Bent Brigham Hospital, assistant in surgery, Charles L. Dummier, Jr., M.D. Harvard '38, now at Peter Bent Brigham Hospital, assistant in surgery, and Horace E. Campbell, S.B. University of Nebraska '25, now at Harvard Medical School, research fellow in surgery.

The New England Society of Psychiatry held its annual meeting at Danvers State Hospital, Hathorne, on April 25. The following were elected to office: president, Dr. Roy D. Halloran, Waltham, Massachusetts; vice-president, Dr. George E. McPherson, Belchertown, Massachusetts; secretary-treasurer, Dr. Bardwell H. Flower, Boston; councilors, Dr. Charles H. Dolloff, Concord, New Hampshire, and Dr. George A. Elliott, Middletown, Connecticut.

CORRESPONDENCE

GERIATRICS

To the Editor Your editorial, "Geriatrics," in the April 18 issue is particularly interesting to us here because the term, "geriatrics," was coined by one of our graduates, Dr. I. L. Nascher, of the class of 1885. And it is for this reason as well as for purposes of accuracy, that we call your attention to the following:

In 1928, the entire Annual Graduate Fortnight at the New York Academy of Medicine was given over to the topic, "Problems of Aging and of the Old," and you will find an account of the sessions in *Bulletin of the New York Academy of Medicine*. In *Annals of Medical History* (NS 10:324-335, 1938) you will find a paper by J. T. Freeman on "The History of Geriatrics." On page 333, reference is made to Dr. Nascher and his coining of the word, geriatrics. Dr. Nascher himself has written a book, *Geriatrics* (Philadelphia: P. Blakiston's Son & Co., 1914).

You may be interested to know that Dr. Nascher is still living and is working on Staten Island.

HELEN BAYNE, *Librarian*,
New York University College of Medicine.

ARTICLES ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY, AMERICAN MEDICAL ASSOCIATION

To the Editor In addition to the articles enumerated in our recent letter the following have been accepted:

Abbott Laboratories

Ampules Ephedrine Sulfate—Abbott, 0.025 gm. ($\frac{3}{8}$ gr.), 1 cc.

Ampules Gold Sodium Thiosulfate—Abbott, 0.075 gm.

Lakeside Laboratories, Inc.

Ampules Caffeine with Sodium Benzoate—Lakeside, 0.24 gm. ($3\frac{3}{4}$ gr.), 2 cc.

Ampules Caffeine with Sodium Benzoate—Lakeside, 0.49 gm. ($7\frac{1}{2}$ gr.), 2 cc.

E. S. Miller Laboratories, Inc.

Compressed Tablets Sulfanilamide—Miller, 5 gr.

Sharp and Dohme

Elixir Propadrine Hydrochloride

E. R. Squibb and Sons

Amniotin in Oil, 5000 international units

Ephedrine Alkaloid—Squibb

Ephedrine Compound Inhalant—Squibb

Ephedrine Inhalant Plain—Squibb

Ephedrine Sulfate—Squibb

Capsules Ephedrine Sulfate—Squibb, $\frac{3}{8}$ gr.

Capsules Ephedrine Sulfate—Squibb, $\frac{3}{4}$ gr.

Tablets Thiamin Chloride—Squibb, 10 mg.

Tablets Thiamin Chloride—Squibb, 3 mg.

Thiamin Chloride Solution, 5 cc., 10 mg.

Thiamin Chloride Solution, 5 cc., 25 mg.

Thiamin Chloride Solution, 5 cc., 50 mg.

Thiamin Chloride Solution, 10 cc., 10 mg.

White Laboratories, Inc.

White's Thiamin Chloride Tablets, 1 mg.

Chicago, Illinois

REPORTS OF MEETINGS

SUFFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Suffolk District Medical Society, held at the Boston Medical Library on January 31, was devoted to papers presented by the staff of the Children's Hospital.

The first speaker was Dr James L. Gamble, and his subject "Certain Features of the Water and Salt Exchange." It was pointed out that the kidney mechanism for the maintenance of fluid balance and ionic equilibrium is a slowly acting one, whereas the transfer of water across the cellular barriers is a rapid one which temporarily compensates for osmotic changes. The interstitial fluid, which amounts to three quarters of the extracellular fluid affords an excellent buffer for these changes and is consequently of variable volume.

Experiments on the sodium balance showed that there is an extreme variation in the urinary excretion of sodium while the intracellular ions are removed in essentially constant amounts. These measurements were interpreted as indicating a considerable fluctuation of the volume of extracellular fluid even under quite normal circumstances.

Dr Louis K. Diamond presented the second paper on "Variability of the Clinical and Hematological Manifestations of Leukemia in Childhood." It was suggested that the bizarre presenting symptoms and subsequent course of these conditions in children make untenable the former classifications by the type and number of cells alone. The classic clinical picture of leukemia is often a late manifestation in this age group whereas the chief complaint at onset may be pallor, easy bruising, bleeding from the alimentary tract, pain in the joints or abdomen, or merely anorexia and loss of weight. Consequently Dr Diamond recommended a reclassification by the clinician in addition to the hematologist, who not infrequently cannot properly classify the disease by its cytology alone.

As further support for his proposal, the speaker cited various animal experiments which have substantiated the claim that the leukemias are divisible into clinical groups. Heredity as an etiologic factor does not play the dominant role in human leukemia that it does in inbred mice. The report of familial cases, however, does seem to indicate some hereditary tendencies. A very important feature of leukemia in mice produced experimentally by inoculation is that living cells must always be transmitted, and it is these rather than the host cells which progress malignantly. Furthermore, the course and characteristics of the disease in such animals can be moderately well predicted by knowing the cell type, the manner and site of injection, and the condition of the host (infection previous roentgen therapy and so forth).

Dr Diamond concluded that experimental and human spontaneous leukemia have much in common and suggested, therefore, that the human disease may be considered to be a malignant process, that heredity plays a minor etiologic role in the spontaneous disease, and that a careful history and observation of the onset and course enables one to place most cases in several large categories similar to those proposed for the disease in mice.

Of 150 cases of leukemia observed at the Children's Hospital he was able to distinguish ten distinct groups of 6 to 12 cases each. Examples of four of these groups were given. In the first group were cases with only slight enlargement of the lymph nodes and spleen but with bleeding and anemia as outstanding manifestations. There were a rapid fatal course, a marked leukocytosis and a diffuse infiltration of all tissues with leukemic cells at autopsy. The patients in the second group had moderate enlargement of the lymph nodes and spleen at first but usually presented themselves because of anemia or abdominal pain. The course was one of rapid increase in size of the spleen and the abdominal nodes, with a high white-cell count and fever. The third type was characterized by an early resemblance to rheumatic fever and by ecchymoses. These children ran a more subacute course and revealed a nor-

mal or low white-cell count, with a few abnormal cells. There might be terminal anemia of an aplastic sort, which was explained by the postmortem finding of diffuse extensive infiltration of the bone marrow. The final major group often had a primary pulmonary complaint and then progressed slowly with moderate anemia and leukocytosis. Autopsy findings were usually marked by diffuse leukemic infiltration particularly in the thoracic cage.

The next speaker was Dr Allan M. Butler who discussed "Apparent Ascorbic Acid Concentrations in Terms of Plasma, Red Cells and White Cells." Dr Butler stated that low plasma ascorbic acid values are not necessarily indicative of deficiency of vitamin C but that high levels do rule out this condition. More accurate information concerning the state of vitamin C nutrition is provided by analyses of whole blood or the buffy layer of centrifuged whole blood.

The most instructive result of the study of the partition of ascorbic acid was that showing high values in the white layers of centrifuged oxalated blood. The ascorbic acid content of the platelets and white cells from patients with leukemia ranged as high as 140 mg per 100 cc. In scurvy the concentration in platelets and white cells dropped to zero. In deficiency states the concentration of ascorbic acid in the platelets and white cells furnishes an index of vitamin C nutrition that extends beyond that provided by plasma values. If a whole-blood analysis is used as an index the blood must be saturated with carbon monoxide before precipitation in order to prevent oxidation of the ascorbic acid and account should be taken of any elevation of the leukocytes due to infection or leukemia.

The final paper of the evening on the "Criteria for Ligation of Patent Ductus Arteriosus in the Light of the First One and a Half Years Experience" by Dr J. P. Hubbard and Dr R. E. Gross was delivered by Dr Hubbard. It was stated that, on the basis of experience up to date, ligation of the ductus has proved of great value and is indicated in carefully selected cases. The diagnostic criteria were briefly reviewed. These consist primarily of the characteristic thrill and murmur. A bulge of the pulmonary cone may or may not be present in children. Confirmatory diagnostic signs, which when present are of great significance in the selection of patients for operation appear if the shunt is large enough to throw an undue burden on the heart and circulation. These signs include pulmonary congestion seen by x-ray peripheral signs of aortic regurgitation and in the child delayed physical development, the latter resulting from impaired systemic circulation. When the circulation is severely overburdened, the usual signs of congestive failure may appear.

The surgical technique developed by Dr Gross consists of a left pleural approach with collapse of the left lung and dissection of the ductus.

Dr Hubbard described the results in the first case. These included the disappearance of murmur and thrill, the return of the blood pressure to normal, gain in weight and so forth. Dr Hubbard pointed out that the incidence of subacute bacterial endocarditis, as given in Dr Maude Abbott's series and more recently in Dr Bullock's series, does not represent the actual chance the patients have of developing this complication. Both these series are of selected cases gathered from the literature. The cases selected by Dr Gross have all presented evidence of an undue strain on the heart. It is to be hoped that these cases will remain free of bacterial endocarditis, but it is appreciated that years of observation will be needed before this latter point can be definitely established.

Of the 9 cases operated on to date by Dr Gross, 1 was associated with other anomalies, there was 1 postoperative death. Seventeen additional cases are known to have been operated on elsewhere throughout the country. Of these there were 2 postoperative fatalities. In the light of present knowledge and experience, ligation of the patent ductus arteriosus in those exhibiting cardiac insufficiency as a complication was recommended as a beneficial and reasonably safe measure.

WILLIAM HARVEY SOCIETY

A regular meeting of the William Harvey Society was held at the Beth Israel Hospital on February 9, with Dr David Rapport presiding. The speaker of the evening was Dr Alfred M. Richards, whose subject was "Kidney Function." Dr Richards reviewed the history of the subject and of his own researches in the field. He also cited the evidence for his theory of the mechanism of kidney function, which, briefly, consists of a filtration through the glomeruli of all non-colloid constituents of plasma and the selective reabsorption of the threshold substances from the tubules.

Other studies of the speaker have proved that the glomerular filtrate is alkaline like plasma rather than acid like urine, and that the urinary flow is proportional to the blood pressure rather than to the blood flow. The latter was demonstrated by perfusing a rabbit's kidney in situ, while maintaining by a pump a constant flow despite changes of renal pressure.

NOTICES

BOSTON CITY HOSPITAL

The next staff clinical meeting of the Boston City Hospital will be held in the Cheever Amphitheater, on Thursday, May 23, at 11 30 a.m.

PROGRAM

Symposium on Vitamins

The Surgical Significance of Vitamin C Dr Charles C Lund.

Vitamin A Deficiency in Man. Dr Harold J Jeghers

Nutritional Polyneuritis Dr Arnold P Mecklenjohn.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, May 22, from 2 to 4 p.m. Drs Robert Zollinger and C. A. Janeway will speak on "Jaundice."

Physicians and students are cordially invited to attend.

MEDICAL LIBRARY ASSOCIATION

The fortysecond annual meeting of the Medical Library Association will be held at the University of Oregon Medical School, Portland, Oregon, on Tuesday, Wednesday and Thursday, June 25-27, under the presidency of Col Harold W Jones, of the Army Medical Library, Washington, District of Columbia. Hotel headquarters will be at the Heathman. The program will include talks on the literature of epidemiology of plague, tularemia and Rocky Mountain spotted fever, a symposium on investigations in local medical history, and problems in bibliography based on a study of terminology in the field of nutrition.

DEDICATION OF OSLER MEMORIAL

The old autopsy house where Osler worked at Blockley has been restored as the Osler Memorial Building, and will be dedicated on the grounds of the Philadelphia General Hospital, at Curie Avenue, near Thirty Fourth and Pine streets, Philadelphia, at 2 p.m. on June 8.

Original furnishings, including the necropsy table, have been collected. The painting by Dean Cornwell, N.A., of New York City, entitled "Osler at Old Blockley," later to be hung in the building, will be on exhibition during the celebration.

There are facilities in the building for the housing and preservation of relics of old Blockley, as well as Osteriana. The committee would welcome any additions to this collection.

A cordial invitation is extended to those who are interested, and especially those who are planning to attend the meeting of the American Medical Association in New York City, June 10 to 14.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The nineteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held September 2-6, at the Hotel Statler, Cleveland, Ohio. Mornings will be devoted to the annual instruction course, and afternoons and evenings to scientific sessions. The seminar and convention proper will be open to physicians and qualified technicians.

For information concerning the seminar and preliminary program of the convention proper, address American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MAY 19

MONDAY MAY 20

7 p.m. South Boston Medical Society Harvard Club Boston.

TUESDAY MAY 21

*9-10 a.m. Arthritis clinic Dr Walter Bauer Joseph H. Pratt Diagnostic Hospital

WEDNESDAY MAY 22

*9-10 a.m. Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital

*2-4 p.m. Jaundice. Drs Robert Zollinger and C. A. Janeway Peter Bent Brigham Hospital

THURSDAY, MAY 23

*9-10 a.m. Cardiac clinic Drs H Magendantz and A. Zethin. Joseph H Pratt Diagnostic Hospital

11 30 a.m. Boston City Hospital staff clinical meeting

FRIDAY MAY 24

*9-10 a.m. The Origin Diagnosis and Treatment of Primary Biliary Tumors Dr Oscar Hirsch Joseph H Pratt Diagnostic Hospital

SATURDAY MAY 25

*9-10 a.m. Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital

*Open to the medical profession.

BOOK REVIEWS

The Dysenteric Disorders. The diagnosis and treatment of dysentery sprue colitis and other diarrhoeas in general practice Philip Manson-Bahr. 613 pp. Baltimore William Wood & Co. 1939 \$8.00

This volume is based largely on the author's experience of thirty years of practice and study in the Orient and in London. The subject matter covers a wide range of conditions including bacillary and amebic dysentery Asiatic cholera celiac disease and some of the helminthic infections. The author thoroughly versed in his field, may have underestimated the difficulties confronting less experienced men who would value a full expression of personal opinions and preferences.

In general the therapy of these various disorders is presented from the standpoint of embracing all points of view. For the treatment of amebic dysentery preference is given to emetine or its modifications and to yatein, although fifteen or more drugs and other substances are considered. Among those relegated to a rank of lesser importance is carbarsone, although the effectiveness of this drug has been demonstrated to the satisfaction of American physicians.

Full consideration is given to various procedures for treating Asiatic cholera. Intestinal disinfection at best a difficult undertaking, is included as one of the important principles in its treatment.

The author considers that the literature contains a welter of conflicting views concerning the etiology of sprue. He presents the conception that the true etiology is a specific virus affecting the intestinal mucous membrane, this interpretation being based on clinical observations. In treatment, considerable emphasis is placed on the difficulties encountered in selecting a suitable diet from the many which have been recommended. Liver soup in small daily amounts is included in one set of diets, and liver extract is added to some of the high-protein diets, using the equivalent of five eighths of a pound of liver daily. Among the many pages devoted to the dietary treatment of sprue, the reader should direct his attention to the paragraph concerning the parenteral administration of liver extract.

Schistosomiasis appears under the designation of bilharziasis and is accompanied by an inaccurate consideration of dates that are essential.

The appendices, enriched by some excellent illustrations, describe clearly some of the important protozoa and bacteria and the laboratory procedures which are useful in diagnosis. An extensive bibliography is presented, but it does not fully solve the difficult problem of well selected representation.

Supervision in Public Health Nursing Violet H. Hodgson. 376 pp. New York The Commonwealth Fund 1939 \$2.50

This book is a set of admirable rules for the proper supervision of public-health nursing. One is not in a position to challenge the validity of Mrs. Hodgson's principles, which are based upon unusual opportunities of observation in what is known as the field. It is the set of the author's mind, the whole unconscious atmosphere pervading the book, which engenders the perverse reaction that perhaps records, the clinic the director case conferences or even public health nursing itself may just conceivably not be among the eternal virtues of life requiring a "philosophy of supervision" (Chapter IV). In this as in any other field where there is a job to be done, it is to

be hoped that a man or woman may be found to do it without the inevitable necessity of such elaborately specific training as is demanded by Mrs. Hodgson.

The volume is replete with diagrams of the type so dear to the heart of the late Dr. Elmer E. Southard—little boxes labeled "board," "assistants to commissioner," "field nurse in charge" and so forth, connected by unmistakable straight and dotted lines. These are clear, specific and well planned, but not very interesting.

The results of Mrs. Hodgson's occasional incursions into the field of semasiology are not happy. "The original meaning of a Staff," she says (page 68), "is something to lean on." This is a good WPA doctrine, but as a matter of fact, the original meaning of "staff" is a cudgel, or a stick which shows its bearer to be a person of authority.

If this book were translated into German, its adherence to the idea of the *Führer Prinzip*—despite its frequent allusions to what the author terms "Democracy"—would be apparent and acceptable. This criticism is not intended necessarily to be derogatory.

Every supervisor of public-health nursing will do well to read and study this manual. If she can bring to her work in addition to Mrs. Hodgson's stern requirements a sense of humor and proportion, she will indeed be worthy of her hire.

Nursing Mental Diseases Harriet Bailey Fourth edition 264 pp New York The Macmillan Co., 1939 \$2.50

This book is meant to be used as a textbook in nursing schools. Miss Bailey is admirably qualified for authorship of such a book by her years of experience in teaching the subject. A graduate of Johns Hopkins School of Nursing, she has been assistant superintendent of nurses at the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, principal of the Training School for Nurses at the Manhattan State Hospital, New York City, a member of the Department of Medical Information and formerly nursing editor of the *International Journal of Public Health* and director of nursing education at Bellevue and allied hospitals in New York City.

The author has covered the ground of psychiatric nursing thoroughly, each phase of mental illness and disease is painstakingly dealt with, causes are delineated, symptoms discussed, and treatment and nursing care described.

The first chapters deal with the history of the care given the mentally sick from ancient times down to the present day, with its improvements in the understanding of mental ills and their relief, as well as preventive measures of mental hygiene. She also takes up the legal aspects of the subject, giving the legal definition of insanity and explaining the regulations for commitment and other legal procedures touching on mental disease.

From there she goes on to the development of the personality, an understanding of which she believes to be extremely necessary to good psychiatric nursing. This chapter takes up the definitions of such psychological terms as unconscious and subconscious mind, complexes, emotional conflicts, compensation and sublimation.

The book then gives specific causes for mental illness, a general classification of the different disorders and the difference between psychoses and the psychoneuroses, before taking up a detailed account of the symptoms of each of these illnesses.

There is a chapter which discusses the qualification for mental nursing, the handling of patients, the administering and preparation of foods for different types of patients and the care of everyday functions, bedsores, con-

vulsions and the like. There is also one entitled "Dangers and Precautions—Accidents and Emergencies," in which Miss Bailey gives warnings for the dangers to be watched for and circumvented and describes first aid treatment of all kinds, to be given before the doctor arrives.

The main portion of the book is, of course, given over to the description of the different psychoses and psychoneuroses, their symptoms and the treatment and nursing care needed in each. Alcoholism, epilepsy and mental deficiency are included in the list.

The last three chapters describe therapeutic measures, physiotherapy and mental hygiene. There are also a bibliography and a glossary in the back of the book which should prove helpful to student nurses.

Ophthalmology Clio Medica 20 Burton Chance. 240 pp. New York Paul B. Hoeber, Inc., 1939 \$2.00

Chance's book is an outline of the history of ophthalmology. Like other books in the Clio Medica series it is pocket size and inexpensive. It is necessarily brief and conspicuously devoid of lengthy references and annotations. Ophthalmologists, opticians and others interested in ophthalmology's background will find it very readable.

The material in the book is arranged in more or less chronological order and therefore permits either sequential or reference reading. The first chapter describes ophthalmic practice, so far as is known, in the Mesopotamian valley from 2250 B.C. on. Then follow in order similar descriptions of ophthalmology in Egypt, China, Greece and Rome, and a description of ophthalmology in the Arabian, Medieval, and Renaissance periods. The modern period, according to the author, begins with the establishment of the Vienna School in 1773. The second half of the book is devoted to the historical development of our knowledge in regard to individual diseases, phenomena, methods of treatment and particular sociologic aspects of ophthalmology. In bringing the material up to date numerous references are made to persons now living and still actively engaged in molding the historical course of ophthalmology.

Aside from learning many interesting facts, one gets certain general impressions from a survey of this kind. One thus obtains the impression that ophthalmology did not develop as a logical specialization of medicine but rather that it evolved from a sort of quackery and charlatanism. Instances like the founding of the Vienna School by the pupils of Baron Wenzel, an itinerant cataract coucher, are the cornerstones of ophthalmology. The recognition of the specialty as a legitimate and honorable branch of medicine is of relatively recent origin. At a time like the present when further basic changes in the practice of medicine are being contemplated, it is well for all ophthalmologists to have some knowledge of their specialty's history, and this book gives just enough and not too much for the great majority.

Biological Products Louis Gershenfeld. 236 pp New York Romaine Pierson Publishers, Inc., 1939 \$4.00

This is a very valuable little reference work covering all biological products, with detailed descriptions of the manufacture, uses and efficiency of the commoner ones. The author has done an unusually fine job condensing essential information. The pictures are interesting, but seem to the reviewer to add to the expense of publication without adequate return. The book should be extremely useful to the general practitioner.

NUMBER 21

NEW ENGLAND, NEUROSURGERY AND THE NEUROSURGEON*

WILLIAM JASON MIXTER M.D.†

BOSTON

MANY authors have written of the beginnings of medicine in New England, and through their writings we find something of the foundation on which medicine in this corner of the United States was built. We read of the minister physician and the barber surgeon in the early days of our colony. The minister physicians were among the leading men of their respective communities. Theirs was no easy job. They had souls to save as well as lives. Let us not cavil if their theology breathed of hell fire and brimstone and if the purge was the most frequently employed form of medication. What if they did "breathe a vein" for almost any ailment, and what if the barber surgeon did use all sorts of curious and revolting things for dressings? Those were the days of angleworm oil, of nanny tea and other archaic medicaments. Some benighted peoples still use curious forms of treatment. Bear's gall bladders not many years ago had a ready sale to the Chinese doctors of the Pacific Coast. We can say "Oh, yes, the Chinese"—but we had quaint customs here at home. I can remember removing a poultice from a caruncle in my early days—an amateur poultice to be sure. It was offensive to the nose and to the eye and proved to be a large chew of tobacco.

These early members of our fraternity had learned their medicine in England, but when they came to America they left behind much of the quackery and charlatanism that was rife in England during the fifteenth and sixteenth centuries. Remember that this was a new country and that life was cheap and the way of life was hard. They were pioneers and they cut out the nonessentials.

We read of starvation of Indian raids, of the various epidemics that decimated the colonies. The worst of their plagues was smallpox, that dread scourge, that stalked through the settlements in more deadly fashion than an Indian war party. Smallpox took its toll of lives time after time

until Zabdiel Boylston, about 1720, read or heard of direct inoculation with smallpox material. He must have been a courageous man, this Boston physician, for he decided to use this new and almost untried method of disease prevention. Many powdered heads were shaken in disapproval but the experiment was a success. It is an interesting fact that his records of these cases were excellent. His statistics proved the value of inoculation, and his work was accepted here and abroad.

During these years from the establishment of the colonies to Zabdiel Boylston's time we find certain changes in the practice of our profession. The physician continued to be one of the leading spirits of the community. He was prominent politically, but he no longer played the dual role of medical adviser and minister to the soul. We find that medical thought was still dominated by the teachings in vogue in Great Britain, but we find each prominent physician teaching his apprentice or group of apprentices, and also find that many of these young men went to England to complete their education. A few went farther and studied on the Continent. They were independent in medical thought as they were in their politics. They delved into new things in medicine as they explored the terra incognita that lay beyond their settlements. They were still pioneers.

We read of those gallant gentlemen who gave of themselves that these United States should be forever free—names like Warren that have come down from father to son or nephew and still abide on the roster of the Massachusetts Medical Society. We read also of the Loyalists who devoted to King and mother country, followed the English troops—exiles for their political convictions. We may read between the lines and learn that the doctor of those early days was far more a leader in his community than we are—a man of broad education and interests, looked up to and admired for his good works and his leadership. There must have been much of

*The Annual Discourse delivered at the annual meeting of the Massachusetts Medical Society, Boston, May 22, 1940.

†Lecturer in Neurosurgery, Harvard Medical School; chief of neurosurgical service, Massachusetts General Hospital, Boston.

and much of bitterness in 1776, for we read that some of the pupils of the beloved teacher, James Lloyd, sailed for Halifax to lead the lonely lives of exiles. Other pupils, the younger and more radical element, donned the blue and buff of the colonial forces. The doctor's life was a hard one. He stood on his own feet, foursquare to the world, and worked out his problems for himself. He had no assistance from laboratory and roentgen ray and all those things that make diagnosis easier for us.

About the turn of the century, while the states were settling down trying to find out what they had won besides independence, the character of medical education changed. Schools were established and the apprentice system was abolished except for postgraduate education. We looked to England for much of our medical lore, but we as a pioneer community developed our own trends in medicine. That word "pioneer" means much in American life. We can be proud that the members of our profession lived up to their traditions and to the trend of their own times. Untrammelled by the taboos of European medicine, they developed along their own lines.

Many tall tales have come down to us of these old days before 1846, when Morton soaked a sponge with ether that the grand old man of the Massachusetts General Hospital, John Collins Warren, might demonstrate that painless surgery had arrived.

Even the small-town doctor did his investigating, and under difficulties that would make us cringe. There are two treasured legends in my own family, one concerning my great-great-grandfather, Ingalls Kittredge. He practiced in Beverly, and it is said he brushed up his anatomy as occasion offered. One rainy night he crossed the bridge which then, as now, connected Beverly and Salem and drove his shay by devious ways to Peabody, where he met certain grave robbers who delivered to him the body of a recently deceased and, we hope, respected citizen of that rather lonely hamlet. On his way home after midnight with the subject seated beside him, he reached the bridge. The toll gate was open and all was dark. A cut with his whip and the horse galloped out on the bridge. Just before he reached the gate the keeper rushed out and slammed it shut. The sudden stop unseated the doctor's gloomy companion, who pitched forward and nearly went out over the wheel.

Old Ingalls Kittredge must have had a strong and dexterous hand as well as an agile brain. He grasped him by the nape of the neck and pulled him back. "Sit down, ye drunken fool!" was his comment. He paid his toll and drove home.

Can we not take this legend to heart? Even if the night is dark and stormy and the way to our goal long, can we not forge ahead to the increase of our own knowledge and the betterment of our service to our fellow men?

Ingalls Kittredge, his son, also was of an investigative turn of mind. One day he had as a patient a man dying with fever. There was a mass in the right side of the abdomen. He decided there was pus present, and to the horror of his associates he cut into the abscess, washed it with clean water from the spring and drained it with clean tow from the center of the bundle. The man lived, else I might not be here, for the good townspeople of Beverly beset his house at the corner of Essex and Federal Streets with a hangman's rope at hand until it was known the patient was out of danger.

So much for the past. We can see a change—a tendency toward specialization if you will—even from the earliest days of the Massachusetts Bay Colony. At first our predecessors combined medicine with political and religious leadership. By the time of the Revolution they had given up their pastoral activities, then other intellectuals gradually assumed political leadership—medicine is a jealous mistress and will not permit a divided allegiance.

Our heritage, together with that of our predecessors in the last hundred years, is a grand one: self-confidence, leadership, the spirit of the pioneer, coupled with the desire to investigate and the will to achieve. They carried it with them in the migration to the West in the eighteen-forties and fifties, those hardy men of New England. From one of them, an obscure army surgeon at Mackinaw, came the brilliant investigation of gastric secretion that made the name of Beaumont famous. It was not only the adventurers who made the trek across the mountains to the plains. Whole families went, and to one of these pioneer groups that settled on the southern shore of Lake Erie we shall turn later for the greatest of the pioneers in neurosurgery—Harvey Cushing.

Neurosurgery has its beginnings in the cloudy past, before the days of history. This is attested by a collection of Peruvian skulls—one of the treasures of the Warren Museum at the Harvard Medical School. It is interesting to learn that then as now the man with the investigative mind might find that someone else had the same thought. In the museum at Copenhagen last summer I saw skulls from the Scandinavian countries with the same four saw cuts, the same holes, made to let out the evil spirit, and in some of them, as in the Peruvian skulls, the patient had survived the ordeal, for new bone had formed around the edge

of the opening. It is interesting to realize that in all ages and among all people the brain has been known as the seat of consciousness. I suppose that Cain learned this scientific truth when he struck Abel, that is, if he hit him on the head. It is even more interesting to realize the depths of our own ignorance of consciousness, the cause of sleep and so forth. We still have many things to learn. However, that is not the point at the moment. The point is that the priest, the surgeon or someone has been opening the skull since before the dawn of history, probably with the idea of curing some mental ill.

Neurosurgery in America can be said to be the offspring, born in lawful wedlock, of neurology and general surgery, with physiology as godfather. It is difficult to state exactly when and where this interesting event took place.

It seems to me that the organization in Philadelphia during the Civil War of an army hospital devoted to the treatment of nervous diseases both medical and surgical, marks the beginning of the special handling of neurosurgical cases. The men in charge of this project were well suited to carry out the new venture. S. Weir Mitchell was a neurologist and a physiologist, W. W. Keen an enthusiastic and daring surgeon, while George Moorehouse was an able medical man and administrator. The surgical cases treated were almost entirely due to injuries of peripheral nerves. Today neurosurgery is far more engaged with the central nervous system than with somatic nerve fibers outside the cerebrospinal axis.

By 1888 cranial localization and the surgery of tumors had become an important subject for consideration. Reading the transactions of the first meeting of the Congress of Physicians and Surgeons held at Washington in September of that year, we find the record of a symposium devoted to these subjects. Keen and Roswell Park, who were surgeons, took part, as did Charles K. Mills, M. Allen Starr and others, who were neurologists. David Ferrier and Sir Victor Horsley, leaders in physiology and brain surgery, came from England to attend this meeting and here we see again the close association of American and British medicine. We find also in these transactions the mention of a case of brain damage caused by birth injury reported by William N. Bullard in the February 16, 1888, issue of the *Boston Medical and Surgical Journal*; the operation was performed by Edward H. Bradford.

Let us think a moment of how neurosurgery was handled in Boston at that time and for the next twenty-five years. James Jackson Putnam had been appointed "electrician to the Massachusetts General Hospital in 1872 and neurologist in

1873. Since that time neurology had progressed but we find mention of barely a dozen cases of brain tumor in the programs of the Boston Society of Psychiatry and Neurology before 1905. Neurosurgical operations were few and far between, and were performed by the general surgeons at the instigation of and under the direction of the neurologists. However, even then certain surgeons were picked out, or perhaps picked on, by the neurologists to be the operators. As we have seen in the earlier reports, Bradford was one. My father was another. His was an investigative spirit and he delighted in exploring new fields. He obtained from Stone and Webster, then a young electrical engineering concern, a small electric motor, and devised a guarded circular saw with flexible cable which he used to open the skull. I keep the motor and saw as a memento of those early days. We must remember that all surgeons of that day here and abroad had ingrained in them by their predecessors the lesson that one of the prime requisites of surgery was speed. My father had it. Horsley had it. Maurice Richardson had it. With it they combined great deftness and precision. Speed is of great value today, but not so valuable as it was then, for now we have all the modern devices to combat shock and hemorrhage, and anesthesia has become a high art.

I can remember many of those early cranial operations during my work as house officer at the Massachusetts General Hospital, which began in 1906. The commonest was the operation for trigeminal neuralgia—usually the Abbe type, with intracranial section of the second and third divisions of the fifth cranial nerve. My father modified this operation by plugging the foramina with silver amalgam and later with bone wax. I can remember operations for tumor—one in particular on a patient of Dr. Putnam's, about 1908. We operated in a private hospital on Commonwealth Avenue, and Dr. Putnam's office nurse had never seen a brain operation. She stood between the windows of the room, and as the first incision in the scalp was made and the old T-shaped hemostats were applied, she collapsed on the floor with her head in the basin in which the bloody sponges were dropping. Someone dragged her out and that was that.

I also remember etherizing while Maurice Richardson operated for cerebellar tumor—big, red faced with a rolling gait accentuated by an old Potts fracture, he was a splendid general surgeon. There was no head rest. The anesthetist held the patient's head with one hand and the cone with the other, and the orderly or someone else poured on ether when the cone was held out under the edge of the sheet. I nearly drowned and nearly

etherized myself, and had to have a shampoo afterward. My own first attempts at brain surgery were of the same sort. I followed my masters. Their work was good as measured by the surgery of that day. I assisted Horsley in London for three months. Speed was his fetish. A sweeping scalp incision, four saw cuts with a hand saw, three or four taps of mallet on chisel, and a square of bone leaped out. Then came a rapid enucleation and even more rapid closure, all under a stream of weak bichloride solution. A physiologist, a neurologist, a surgeon, all in one, but trained in the old school of surgery.

What of neurosurgery in Massachusetts beyond the few men I have mentioned? Edward H. Nichols and Frederick C. Lund at the Boston City Hospital and others were doing neurosurgery as it came along. At the Massachusetts General Hospital, Charles A. Porter was working with Walter E. Paul, the neurologist, on peripheral nerve injuries and getting quite a series of cases. Not one of these men considered neurosurgery even as his major interest. The neurologists were doing more than the surgeons, for they were truly specializing in their chosen field and pioneering in the diagnosis of neurosurgical conditions and in some instances in treatment. Others besides Putnam were at work. I learned to know and respect Philip C. Knapp and E. Wyllys Taylor for their studies on the brain. Paul, as stated above, was working on the peripheral nerves, and George L. Walton had already published his important paper on cervical dislocations. I have one of the reprints which the latter gave to my father. Were any one of us to write that paper today there is little that we could add to it except some roentgen-ray pictures.

But at this time Harvey Cushing in Baltimore, Charles L. Frazier in Philadelphia and Ernest Sachs in St. Louis were beginning to develop real neurosurgical clinics. Cushing in particular was limiting his work to neurosurgery and modifying the meticulous, painstaking surgical technic originated by Halsted. Brain surgery requires the utmost in gentle handling of tissues, exact hemostasis and the persistence and ability to carry on for hours if necessary. To achieve this end, one must have a surgical team that is near perfection and every aid in anesthesia, instruments and operating-room facilities that modern science can give. Cushing recognized this fact and also the importance of exact and painstaking localization, with the use of every aid to be obtained from neurology and physiology.

Harvey Cushing came to Boston to become Moseley Professor of Surgery at Harvard and to thrill the world with the till then undreamed pos-

sibilities of cranial surgery. To Cushing, Massachusetts owes its supremacy in neurosurgery for many years. To him came patients from all over the world, and the young men flocked to sit at his feet and learn of his art. For with him, neurosurgery became an art. Surgeon, neurologist, pathologist and physiologist, he combined them all. Let us honor with the highest praise this illustrious figure in our profession who so recently has gone from us.

Let us examine the changes in neurosurgery that the seventy-five years from that first war hospital in Philadelphia to the present time have brought.

The pioneers have led us on from small beginnings to great achievements. Peripheral nerve surgery has become standardized. The surgery of brain tumor is on a firm foundation, and the spinal cord, the pituitary gland, even the ventricles of the brain, are open to inspection and treatment if need be.

What has Massachusetts added to the score since Harvey Cushing gave impetus to neurosurgery in this community?

A neurosurgical service is now an important part of many of our large hospitals. Donald Munro, the son of a gifted surgeon, John C. Munro, has taught us much about skull fracture, and also to seek out and find that elusive and treacherous aftermath of head injury, the subdural hematoma. Gilbert Horrax is following Cushing's lead in the surgery of brain tumor. Tracy J. Putnam left Boston last fall to become the head of the Neurological Institute in New York City. There he is carrying on the brilliant research work that he began in Boston. At New Haven, William German and John Fulton are carrying on the Cushing tradition of investigation and brilliant technical achievement. They received their training here in Massachusetts and as New Englanders we can claim them as our own. At the Massachusetts General Hospital we are busy with our problems in relation to the central nervous system. From a few scattered beds neurology and neurosurgery have grown to the status of independent services with a permanent visiting staff and a group of residents. From less than fifty operative procedures a year we have grown to more than that number a month. In the surgery of the sympathetic nervous system James C. White and Reginald H. Smithwick are exploring untrodden pathways.

The specialist does not spring full panoplied: Pallas Athena did from the head of Zeus. He is a long apprenticeship, not to one teacher: in colonial days, but nonetheless an apprenticeship. He must sweat his way through college and medical school with the others who, like himself, b

lieve that the healing art is the ultimate in service to humanity. Then comes his hospital service, his work in allied branches of medicine and finally his residency in his chosen field. Five full years and perhaps more. Then comes the plunge and he is out on his own.

Cushing's clinic at the Peter Bent Brigham Hospital was the first in New England to educate neurosurgeons, and they are following in his footsteps all over the world. Now there are other groups carrying out the same plan. We find these young men in medical schools in large centers and also in the small cities. Some of them have had hard work to get started, owing to professional jealousy and the desire of some of our profession to do everything in surgery whether they do it well or ill. More have been welcomed as helpers in the field and through their efforts the standards of practice in their communities are being elevated. I look forward to the day when the whole of this country will be covered by men trained in this branch of surgery as it is by the exponents of the other specialties.

Prophecy is dangerous and the prophet is often discredited, but I believe that we can see a bit ahead. The malignant gliomas will defeat us. It is for some new pioneer to lead us out of that hornet's nest. The sympathetic nervous system has yielded many triumphs since Royle's ill-starred attempts to modify spasticity brought it to our attention. Fulton at the Peter Bent Brigham Hospital studied one of these early cases and was quick to see the possibilities of its effect on the vascular system. Smithwick and White have added to our knowledge, and I believe there are great possibilities ahead, including control of pain, the amelioration of hypertension and so forth.

The possibility of the surgical treatment of certain forms of insanity is more than a rainbow. Destructive surgery, it is true, but nevertheless it may be the dawn of a new era in the treatment of this tremendous group of sufferers.

Neurosurgery is ever changing. As it goes forward to these new things, it is setting aside and giving to the profession at large certain things that it called its own not so many years ago. Who does the nerve sutures in our great hospitals today? Not the neurosurgeons; no, indeed. The house officer dealing with severed tendons in the wrist picks up and sutures the median or ulnar nerve as a matter of course. The surgeon caring for a fracture of the humerus cares for the musculospiral nerve, and in the war hospitals of Europe the operating surgeons in the mobile units are repairing bullet wounds of nerves and of the central nervous system.

What lesson may we learn from these facts

which I have brought so sketchily to your attention? Neurosurgery has been and is undergoing a period of growth and expansion, partly on account of research and advance by neurosurgeons in their own field, and partly because of the application in neurosurgery of advances in general surgery, in neurology and in physiology. It is by reason of this continuing advance that neurosurgery is accepted as a specialty in medicine. It is not a narrow, hidebound specialty but a broad specialty equipped and able to invade that all important cavity containing the central nervous system and to follow through the body wherever nerve cells send their tendrils. But that is not all. Today the neurosurgeon is going forward as a pioneer, following the precept of all pioneers and blazing out new trails for others to follow. So it is with all specialization in medicine. Specialties will hold unto themselves certain procedures which because of their inherent difficulties or because of the complicated equipment necessary to carry them out, are not suitable for general use. It would be folly for one not especially trained to attempt the surgery of brain tumor, nor could one of us neurosurgeons in his own office perform the miracles of diagnosis carried out daily by the radiologist. As soon as a procedure becomes standardized and can be applied by the profession at large, it should cease to be held and guarded as a potboiler by the specialist. If he waits beside the trail, nursing his little potboiling fire, he will fall behind his brother pioneers and the profession may lack something which they could use for the betterment of humanity.

These are the thoughts that I would leave with you in these closing hours of the 1940 meeting of the Massachusetts Medical Society. All of us are seekers after truth, and especially for that truth which will benefit the health of our fellow men. Ours is a science, an art and not a business. To apply business methods to medicine either by our own volition or by legislation will impede its advance. By giving of ourselves without stint we shall obviate the necessity of such regulation. Surgery is like a great river ever flowing onward. This river is made up of the waters of many streams, and of these neurosurgery is one. Each stream contributes something to the whole and to the smooth course of the river's progress. Any one of us, in practice, in the laboratory, in a specialty or in any of the many branches of medical science, may come upon some hidden spring to add to its volume. Let us, as members of the Massachusetts Medical Society, seek out these hidden springs and share them with the brethren of our profession, to the end that suffering and sickness be lessened in the world.

319 Longwood Avenue.

MINOR CAUSALGIA A HYPERESTHETIC NEUROVASCULAR SYNDROME*

JOHN HOMANS, MD

BOSTON

THERE is a very peculiar circulatory disease or symptom-complex which affects the extremities and which is marked especially by exaggerated sensitiveness of the skin. This hyperesthesia is such that any touch excites a sort of pain which the patient very much dreads. There often is but need not be spontaneous pain. Nevertheless it is so difficult to carry on everyday affairs without some contact of the part that in many a case the patient is made uncontrollably nervous, depressed and apprehensive. There are serious cases and mild ones, and it is the serious ones which have made the mild ones understandable.

Many years ago, S. Weir Mitchell¹ described the bad sort as causalgia, that is, burning pain. Those of you to whom this term means anything at all will recall that the word referred to a state of glossy redness of a hand or foot, atrophied soft parts, tapered digits, and nails much curved transversely. The burning pain, always present, was comparatively bearable until a touch or even a sound, a draft or a jar caused an agonizing increase. The patients, who were always wounded soldiers, soon became invalids, carrying about a bottle of water and a sponge with which they kept the limb moist at all times.

Mitchell's cases all resulted from wounds received in the Civil War and very little attention was paid to his descriptions until the War of 1914-18 produced a new and abundant crop. As a rule, a large nerve had been injured, very often some part of the brachial plexus, though if one nerve alone were involved, it was usually the sciatic or median. However, as experiences multiplied, it seemed that actually no nerve need be wounded. An artery might be damaged, and as the early symptoms were studied, the cyanosis, the sweating, the paroxysmal nature of the pain, all gave the impression of a sympathetic disorder. At least they did so to René Leriche,^{2, 3} the champion of the sympathetic system as a participator in pain of all sorts. Leriche suggested that arterial wounds were really at the bottom of causalgia and pointed out that the median and sciatic nerves, and of course the brachial plexus, whose injured nervous tissue had seemed at first the

basis of the lesion, have an abundant arterial supply.

It is now well known that arteries are well furnished with sensory filaments, and it has been established (Moore⁴) that these filaments travel into the spinal cord with the posterior, or sensory, roots. How such fibers make reflex arcs with outgoing vasomotor nerves, the classical sympathetic system is, for the moment, unimportant. There probably are reflexes traveling by way of the spinal cord and there may even be local reflexes through plexuses upon the walls of the larger vessels. In any case, signs of sympathetic irritation, that is, sweating and peripheral vascular spasm, can be brought on by central going impulses originating in and about the walls of the arteries and, for that matter, the veins. This is not the place to discuss the problem of why some of these reflex sympathetic disorders are painful and others not, why some leave the skin hot and others cold, why some are attended by edema and others by bone atrophy, why some appear to represent, in addition to everything else, paralysis of great mixed nerves. All are dysfunctions, into which the sympathetic system, primarily a vasomotor mechanism, enters in a very mysterious manner. How, for instance, is it related to pain? Clinical and physiological observations must in time give answer. At least it is fortunate that the causalgia-like states can be relieved, or at least improved, by a procaine block of the sympathetic supply to the limb in question, and that the relief lasts for at least the duration of the block. A clear case of pain and hypersensitiveness due to pure arterial irritation is the following.

A middle-aged man had suffered an arterial embolism. The embolus had become fixed in the left radial artery, which felt like a pencil, and could be followed without pulsation into the anatomical snuffbox. The hand was cool, a little pale, cyanotic and agonizingly sensitive to the touch. Two of the fingers, held partly flexed, were especially blue, cold and so very tender that the man guarded them at all times and refused to allow them to be straightened. When the plugged radial artery was resected under procaine, a sudden and dramatic change occurred. The hand not only felt comfortable to the patient but could now be freely handled. The color of the fingers at once improved.

Thus, fingers which were tributary to no outgoing nerves which could possibly have been influenced by the arterial resection were relieved of a painful vasospasm by the interruption of impulses travel-

*The Presidential Address delivered at the annual meeting of the New England Surgical Society, Salem, Massachusetts, September 29, 1939.

ing centrally along an artery. The accompanying anatomical diagram (Fig 1) explains this contention.

One more bit of explanation. If a blood vessel is bruised or shocked by a bullet without suffering an actual wound, it goes into a state of spasm and

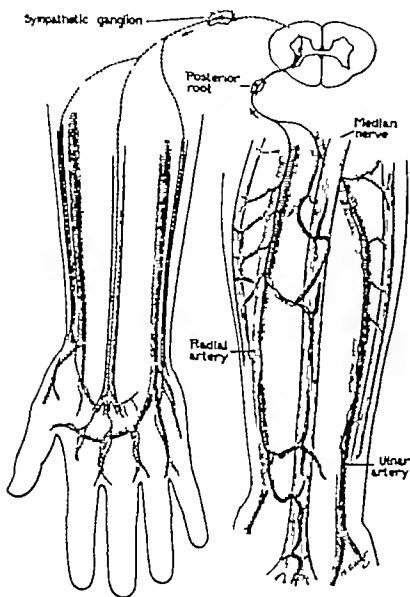

FIGURE 1 A Diagram Representing a Possible Course of the Reflex Impulses Responsible for Causalgia Traumatic Edema Reflex Dystrophy and So Forth

In the limb on the right the size of the median nerve and of the radial and ulnar arteries is exaggerated. The sensory (?) nerves of the arteries are shown in solid black lines and the relation of these nerves to the small arteries of the median nerve can be seen (no attempt is made to show the arterial supply with its attendant nerves for the radial and ulnar nerves)

The nerves pass centrally along the arteries enter the spinal cord in the posterior roots connecting with outgoing sympathetic fibers. The supposed course of the reflex is indicated by arrows.

The sympathetic fibers are distributed via the great mixed nerves to the periphery supplying the vessels of the hand in definite anatomical fields identical with the sensory distribution.

the tissues peripheral to the point of contact become pale, cyanotic and numb, perhaps absolutely insensitive. This is an acute direct and probably local arterial spasm. Moreover it is often temporary. But if a blood vessel is irritated by pressure, or by minor infection, if the tiny nerves

about a good sized artery are teased, or if this teasing is extended to a multitude of small vessels in a limb, there may arise one of these strange, hyperesthetic, atrophic, sometimes edematous states which I am to describe to you. I will quote you one more case to illustrate the effect of a lesion affecting apparently the smaller blood vessels. This is taken from a publication of Lehman.⁴

D. E. D. a schoolgirl of 18 had suffered, 4 months before coming under observation, a punctured wound by a crabapple thorn upon the ulnar border of the right forearm. This had become infected and had been subjected to exploration and drainage. A sinus had been left surrounded by induration heat and redness which extended halfway to both wrist and elbow. The patient feared to have the forearm touched and could barely move the wrist and fingers. During the following 7 months, four operations for drainage were performed. Almost a year after the original injury the forearm and upper arm were swollen and doughy up to the axilla. Pain was increasing. The fingers were cool. The right radial and brachial arteries pulsated (to the touch) less strongly than those of the left hand. Though one of the old incisions was unhealed, the temperature and leukocyte count were normal. Amputation had been suggested.

On the ground that the condition resembled the "trophic edema" of some war wounds, and because tissue removed at the last operation had shown a perivascular inflammation a periarterial sympathectomy was performed upon the right brachial artery. Two days after the operation the fingers were a little less stiff and tenderness of the forearm had diminished. Six weeks later motion at the elbow was free and that of the fingers was continuing to improve. Swelling had disappeared and the skin had become warm and dry. The wound had healed. In 6 months, except for some weakness the extremity was normal. The disease had been cured by interrupting what seem to be ingoing arterial nerves.

That there is something basically at fault about the nervous systems of certain of the individuals affected, is probable. Some are insurance problems. Others have grudges against the world, or are perhaps stupid or even criminal. It is easy enough to find fault with anyone who suffers from a disorder which seems to have no reasonable origin. For all of the ailments which touch off the causalgia like reflex are commonplace and ordinarily are recovered from in a commonplace way. The reason that the strange states they occasion are not more often recognized is because of our extraordinary, indeed, infernal obstinacy in trying to fit things into categories. We think and teach that we can catalogue every diseased state we see. If we cannot catalogue it, we say it is not a diseased state at all. I suppose that in my everyday clinical experience, I am unable to explain at least thirty per cent of the patients' complaints. In this thirty per cent are included states which others doubtless understand and which would be clear to me if someone would lead me by the nose. I judge that to this "thirty per cent"

of many of you are included the reflex sympathetic disorders which are the subject of these remarks

In recounting underlying causes I could begin with fractures, or thrombophlebitis or minor burns, but actually I will begin with a dog-bite

M F D, a single woman of 37, was bitten on the back of the right hand by a dog. A local cellulitis

FIGURE 2 M F D An Instance of Mild Causalgia Following a Dog Bite

Notice the smoothness of the skin of the right hand as compared with that of the left, especially the lack of transverse wrinkles over the interphalangeal joints. This photograph was taken five months after the bite was received

rapidly developed. She entered the hospital 24 hours later. Her axillary lymph nodes were enlarged and her fingers stiff. She left the hospital in 3 days and soon seemed to have fully recovered, but 4 months later she returned. A few days earlier, the back of the right hand and thenar space had swollen. The fingers were a little bluish. They were held straight, the thumb adducted as in a median paralysis, the typical causalgia position. There was a brownish discoloration about the wound, which discharged a little serum. The x-ray showed some decalcifications of the bones and narrowing of the joint spaces. There was an intense hyperesthesia of both hand, fingers and forearm, yet light touch was poorly felt in the area of excessive sensitiveness to scratching or gentle pinprick. The patient was treated by hot soaks, the hand and forearm kept in a sling.

Two months later, that is, 5 months after the original injury, the patient was still unable, because of hyperesthesia, to use her hand. Actually, she was considerably

improved. There was a little brownish discoloration about the bites. The skin of the hand and fingers was smooth, as is shown in the photograph (Fig 2). It was a little warmer to the touch than the other hand. At this time, a sympathetic block of the stellate ganglion completely removed, for the moment, all the sensitiveness to touch, pinching and pinprick. A rise of temperature to over 90°F showed that a full sympathetic paralysis had been secured. The hand felt dry and hot. From this time on, improvement was steady and in a week or two the woman was at work again.

Here, then, is a mild causalgia, due to a (streptococcal?) infection following a dog-bite, and showing the typical smooth, hypersensitive skin, partial muscular paralysis and bone atrophy. There is a tendency to spontaneous recovery which the sympathetic block seems to have hastened.

The next is a case of a very different sort. At first sight, it seems hardly possible that it is related to the type of causalgia first illustrated.

J D T, a man of 30 years of age, about 2 years before was said to have strained his back lifting and was then discovered to have an inguinal hernia, which was believed to have been caused by the strain. Actually, his discomforts were probably due to a fractured lumbar transverse process which was only discovered later. However, an operation for hernia was performed and was followed by a right-sided femoriliac thrombophlebitis. The thrombophlebitis left behind a leg which gave him an extraordinary amount of trouble. The lower part was slightly swollen and cyanotic, but the chief complaint was of hyperesthesia and pain. He not only suffered spontaneous cramps in the early morning but from a heavy numb feeling on walking. The purple color underwent a disagreeable red reaction on exposure to the sun. Subjectively, the foot felt cold.

Examination showed a diminished arterial oscillation in the right calf, equal posterior tibial arteries and a diminished right dorsalis pedis pulsation. Brisk walking brought on the numbness and increased the coldness of the right leg. The hyperesthesia was especially bad on squeezing the calf, as with a blood pressure cuff. It included his whole leg, extending up to the right flank and back, the region of his fractured transverse process. It even spilled over into the left side of the back. The patient was unhappy, apprehensive and demoralized.

A right lumbar sympathetic block gave a typical rise of surface temperature for the right foot and relieved most of the hypersensitiveness. For perhaps 48 hours, the cramps and hyperesthesia disappeared, but at the end of this time both troubles recurred.

In this case, it is clear that the irritating lesion is perivascular, that is, about the great vessels in the region of the groin and pelvis, the scene of the thrombophlebitis. Leriche would advise, I think, separating the artery and vein (dividing the vein?) and a lumbar sympathectomy, and doubtless a very considerable procedure may be necessary to interrupt the vicious impulses. I have seen a somewhat similar result follow an axillary thrombosis.

In the two following cases, the causalgia is supposedly due to nerve injury. The first is of median

origin, the second is presumably due to division of the small sensory nerves upon the two sides of the outer phalanx of the thumb.

E. A. D., a married woman of 50 or so had long haunted the outpatient department complaining chiefly of arthritis. Recently she had suffered a Colles's fracture of the left radius with marked posterior displacement. Reduction secured fair position and the hand was immobilized in acute flexion. Whether it was the initial injury or the flexed position which brought on the subsequent difficulties is not clear supposedly the acute flexion, especially since it has been shown that in this position the median nerve is apt to be compressed between the hard edge of the transverse carpal ligament and the lower edge of the radius. However that may be, the fingers rapidly swelled, pain was severe and the palmar aspect of the wrist became blistered. A neutral position was at once adopted but at the end of 6 weeks little motion had returned to the fingers and wrist. The hand was painful and edematous. Hyperesthesia of the hand and wrist was extraordinarily severe. The forefinger could not even be touched.

A procaine block of the sympathetic supply to the arm completely relieved all pain and sensitiveness, restoring much freedom of motion. The relief was, of course, only temporary, but from this time on the patient began to improve. She has since had her ups and downs, but all that is left is a somewhat numb prickly feeling in the tip of the forefinger and thumb. That is to say the causalgia is gone. The aftermath of a partial median nerve paralysis remains.

The last case to be quoted is that of C. O., a married woman, 30 years of age, who had been operated upon 4 months earlier for a felon of the right thumb. A "fish-mouth" incision had been made and had healed promptly but increasing pain and tenderness, confined to the terminal phalanx, had then set in so that even the lightest touch had become agonizing. The patient was unwilling to move the thumb and guarded it at all times.

An upper thoracic sympathetic block brought about a characteristic rise of temperature, that is, complete paralysis of all sympathetic impulses, and during the sympathetic paralysis, hyperaesthesia was dramatically relieved. The outer phalanx of the thumb could be handled and moved freely but it was noted that between the incision and the nail at the tip of the thumb the skin was unpleasantly numb, as in the case of a skin field imperfectly supplied with sensation. During the day of injection the hyperaesthesia gradually returned.

It was held that a periarterial sympathectomy performed upon the radial artery at the wrist, by interrupting incoming impulses traversing the vessel would probably be curative. Accordingly the veins associated with the radial artery the loose tissues about the artery and the adventitia itself were removed for a distance of perhaps 5 cm. The result was as striking as was that of the sympathetic block. All hyperaesthesia disappeared leaving behind the unpleasantly numb area under the edge of the nail. Six weeks later the comfort persisted though the patient still spared the thumb. The relief should be permanent.

You will appreciate, I am sure, how hard it is to see just what goes wrong in such cases, and you will feel this all the more when I tell you that other, somewhat similar results have followed a slight burn of the arm in an epileptic girl an

operation for Dupuytren's contracture of the hand, a cat-bite, the falling of an arm over the edge of the operating table or bed and the dropping of a block of wood upon the instep. Obviously, the sign which is most definitely common to all these cases is the hyperaesthesia. That this is related to a sympathetic dysfunction is suggested by the remarkable effect of a sympathetic block upon the limb involved. However this merely supports Lenche's contention that the sympathetic is concerned in some way with all pain. It does not tell how an infected dog-bite of the back of the hand causes the reflex irritation. It is perhaps safest to believe, for the moment, that perivascular sensitive fibers, whether lying upon a large vessel or surrounding many tiny arteries, whether in the soft parts or in the midst of a great nerve, are able to excite a prolonged, vicious, reflex, sympathetic disorder. The path of this reflex is not evident, but since it can usually perhaps always, be broken by blocking or dividing the sympathetic ganglionic chain, it may well pass into and out of the spinal cord. It can also be interrupted as has been told above, along the course of the principal artery of the limb—the radial or the brachial, for instance, in the case of a causalgia originating in the hand. It is not easy to reconcile this reflex mechanism, which seems to use a sympathetic pathway, with Sir Thomas Lewis's recent observations upon pain and sensitiveness of the parts about an injury. As a result of experiments upon human beings, he finds that pain, tenderness and the vascular flare are related to hitherto unrecognized "nocifensor" nerves, that is, nerves having a function different from the sensory fibers of the skin. He believes that the stimulation of injury excites these widely arborizing neurons, through axon reflexes, to activate in some way the sensory nerves, lowering their threshold to pain. At the same time the nocifensor reaction calls forth a vascular dilatation. Yet its neurons are not a part of the sympathetic system and act in its absence, having their cell bodies in the sensory, posterior-root ganglia. Lewis finds further that these same nocifensor fibers can be irritated to action by injury to a large nerve trunk, so that they may well be responsible for causalgia and causalgia like states. Certainly the mechanism he describes is admirably adapted to setting up and maintaining this peculiar symptom-complex. Unfortunately it still leaves much to the imagination, ignoring the obvious relief offered by sympathetic block whether temporary or permanent. Doubtless, many more painstaking anatomicophysiological researches must still be undertaken.

Whatever their origin, the minor causalgias

which I have described are a cause of much misery. Recently, Livingston⁷ has very fully discussed them. He is particularly interested in discovering the spot from which the reflex seems to have arisen, the point of injury. Indeed, his paper is entitled "Post-Traumatic Pain Syndromes" and he has demonstrated that the injection of procaine into the "trigger point," repeatedly if necessary, may be curative. My own tendency has been to attempt interruption of the reflex arc, at any available point, by procaine block or surgical excision. You will notice, however, that most cases do not come to surgery. The disorder is often functional, not at first, perhaps, but later. It is overlain by hysterical symptoms. It is subject to the "compensation neurosis" so familiar to the insurance companies and their physicians. If you think that for such reasons this is a dangerous field for all who are not thoroughly familiar with it, at least you will agree that it is a fascinating field, and you will realize that the cure of

patients suffering from a causalgia-like state is likely to earn their whole-hearted gratitude. The painstaking study of common ailments is just as full of rewards as it ever was, and the causalgias are rather common in medical and surgical practice today. They certainly fall among the thirty per cent of cases as to which most of us are blind or ignorant. I suggest that you keep them in mind.

EXTREME LEUKOCYTOSIS AND ACUTE HEMOLYTIC ANEMIA ASSOCIATED WITH THE ADMINISTRATION OF SULFANILAMIDE*

Report of a Case

HARRY M. SPENCE, MD,† AND GILBERT M. ROBERTS, MD‡

DALLAS, TEXAS

IN VIEW of the seriousness of the acute hemolytic anemias that occasionally follow the administration of sulfanilamide, the following case seems worthy of record.

CASE REPORT

C. C., a 34-year-old Negro porter, was admitted to the Parkland Hospital on July 29, 1939, complaining of a swelling in the perineum and marked weakness. Several weeks previously, he had developed a urethral discharge, followed by difficulty in urinating. An abscess had appeared in the perineum, which was incised and drained by his local physician 5 weeks before entry. He was given a few "white tablets" at this time, of an indeterminate nature, with no noteworthy effect. Four days before entry, in the Outpatient Department, the perineal abscess had been reopened and the patient started on sulfanilamide. At home, he gradually became weaker and stuporous, and was admitted to the hospital. At the time of the first blood examination he had taken eighty-four 5 grain tablets of sulfanilamide, making a total of 420 gr over a period of 5 days. He had had gonorrhea 14 and 11 years previously, cured by local treatment. Fourteen years before entry he had had a chancre, and had taken antisyphilitic treatment for a year at that time.

The temperature was 101.6°F, the pulse 120 and the respirations 22. The patient was well developed, lethargic and obviously acutely ill. The mucous membranes were extremely pale. The tongue was coated and pale. The lungs were normal. The heart rate was rapid, with a loud systolic murmur at the apex. The blood pressure was 116/52. Examination of the abdomen showed a fluctuant, tender, reddened, subcutaneous mass in the suprapubic region pointing in the midline 5 cm. above the symphysis. The skin of the penis was undermined by a dissecting abscess. The entire perineum was tense and bulging, with several sinuses draining foul, purulent material. The scrotum was markedly edematous. Rectal examination was essentially normal. There was no lymphadenopathy.

Examination of the blood revealed the following: Red blood cells 1,240,000, hemoglobin 21 per cent (Sahli), white blood cells 140,000, of which 36 per cent were segmented polymorphonuclears, 13 per cent juvenile neutrophils, 18 per cent band forms, 22 per cent lymphocytes, 2 per cent monocytes, 6 per cent myelocytes and 3 per cent myeloblasts. The smear showed achromia, poikilocytosis and polychromatophilia. An average of 5 normoblasts was seen in counting 100 leukocytes. Urinalysis showed a cloudy, amber specimen with a specific gravity of 1.011, a ++ albumin test and no sugar. The sediment contained 18 to 20 leukocytes per high power field, a moderate number of erythrocytes and a few granular casts. The urinary findings were considered due to the local infection. Kline, Kahn and Wassermann reactions were positive. Subsequent laboratory data are shown in Table 1. The

elevated blood-nitrogen level was interpreted as being caused by the urinary tract obstruction.

Diagnoses of periurethral abscess, with extension, and acute hemolytic anemia associated with the administration of sulfanilamide were made. The high leukocyte count could not be explained but the possibility of a leukemia as a cause of the whole picture was entertained. In any

in contradistinction to the granulocytopenia that is usually considered a hazard of sulfanilamide administration prompted us to analyze several cases of acute hemolytic anemia reported in detail in the literature.²⁻⁷

The acute anemia is usually ushered in early

event, surgical drainage of the septic areas and blood transfusions seemed indicated.

On the day after admission the patient was given a light nitrous oxide and oxygen anesthesia and rapid, wide incision and drainage of the perineal, scrotal and suprapubic lesions were carried out. An external urethrotomy was also done, through a structured membranous urethra. The patient was given 600 cc. of citrated blood and was returned to the ward in poor condition.

For 48 hours the patient appeared in critical condition. He was given frequent blood transfusions, intravenous glucose and constant inhalation of oxygen through the Boothby mask. On the 3rd postoperative day he showed definite improvement, and thereafter gradually recovered. The urethrotomy tube was removed at the end of a week and the wounds granulated in rapidly. Sounds were passed during the convalescence. The patient was discharged on the 24th hospital day. He has been seen in the Out patient Department, and continues in satisfactory condition.

The acute form of hemolytic anemia following sulfanilamide therapy is one of the most serious complications of this drug. It is to be distinguished from the comparatively slight, slowly developing drop in hemoglobin that commonly occurs when sulfanilamide administration is prolonged for ten days or more. Harvey and Janeway¹ first described the acute anemia associated with sulfanilamide, reporting 3 cases. Later, Wood discussed the condition and reported on 21 cases of acute anemia occurring in 522 patients treated with sulfanilamide, an incidence of 4 per cent. That this figure is probably considerably higher than the average is indicated by the comparatively few reports in the literature and by the fact that at Parkland Hospital, where over 2000 patients have received the drug under adequate precautions, no case of acute hemolytic anemia, other than the one here reported has been encountered.

The extremely high leukocyte count in our case

in the course of sulfanilamide therapy in a patient apparently responding satisfactorily to the medication. Nausea, dizziness, pallor, jaundice, malaise, weakness and fever are clinical manifestations while the erythrocyte count and hemoglobin content of the blood fall rapidly and sharply. The signs of anemia may come on from thirty six hours to seven days after beginning treatment, the average time of the maximum anemia being five days after onset of use of the drug. No case has developed after the first week of treatment. Cases have occurred in patients from ten months to sixty four years of age. The conditions for which the drug was given have been varied, and there is no relation between the occurrence of the anemia and the type of infecting organism.

The process seems unrelated to the dosage of sulfanilamide or to its concentration in the blood. In a twenty-six year-old woman, a severe anemia ensued thirty six hours after the administrations of only 100 gr. The highest blood concentration of sulfanilamide found by Wood in his anemia cases was 107 mg per 100 cc., whereas blood levels as high as 40 mg were observed in patients not developing anemia.

The pathogenesis of the disease is not well understood. That the anemia is due to a rapid peripheral hemolysis is shown by the sudden drop in the hemoglobin and red-cell count, the rise in the icteric index, the presence of excessive amounts of bile pigment in the urine and, occasionally, frank hemoglobinuria. There is no increase in the fragility of the erythrocytes. In the 2 fatal cases reported, necropsy has revealed erythropoietic hyperplasia in the bone marrow, which is the usual response to peripheral blood destruction, and there has been no sign of bone-marrow depression such

as occurs in the aplastic anemia following arsenic or benzol poisoning

Harvey and Janeway point out the similarity of this type of anemia to the hemolytic crises produced by phenylhydrazine, and suggest that susceptible individuals may produce a toxic product from the sulfanilamide having a phenylhydrazine-

*In 7 of the cases myeloblasts, myelocytes and nucleated red blood cells were noted

like action. Wood found that in 4 of 5 patients in whom the drug was repeated after the development of an acute hemolytic anemia during their first course, a recurrence took place. All the evidence would thus seem to warrant classifying this disorder as one of drug idiosyncrasy.

The leukemoid blood picture in our case seems an exaggeration of the moderate to marked leukocytosis in other reported cases (Table 2). We have no explanation of its mechanism beyond suggesting that it may have been simply a concomitant of the marked bone-marrow stimulation and hyperplasia. A leukemoid reaction with sulfapyridine has recently been described by Moody and Knouf.⁸ Some idea of the marrow activity is shown by the occurrence of 52 per cent reticulocytes on one occasion in our case.

The treatment of the acute anemia involves withdrawal of the drug, forcing of fluids and maximum transfusions of blood. The convalescence is strikingly rapid after the patient surmounts the hemolytic crisis. In one of the 2 reported deaths, no blood was available for transfusion, and in the other, the amount of blood given was apparently inadequate.

SUMMARY

The acute form of hemolytic anemia following sulfanilamide therapy is characterized by a rapid fall in the erythrocyte count and hemoglobin content of the blood during the first few days of sulfanilamide administration. The process is apparently a peripheral hemolysis due to an idiosyncrasy to the drug and is unrelated to the dosage, concentration of sulfanilamide in the blood or type of infection. The bone marrow shows evidence of hyperplasia.

An accompanying moderate to marked leukocytosis has been noted as a part of the syndrome, but has not been emphasized. The case reported illustrates the occurrence of a leukemoid blood picture and the marked height to which the leukocyte count may rise in this condition.

REPORT ON MEDICAL PROGRESS

ENDOCRINES THE USE OF TESTOSTERONE*

JOSEPH C. AUB, M.D.†

BOSTON

THE drug testosterone is worthy of lengthy discussion, for when its use is indicated it is powerful and of considerable value. Indeed in my experience this is one of the most potent drugs recently introduced to medicine. Because its effects are so definite and widespread its use should be regulated with careful judgment and understanding. Testosterone is a synthetic preparation apparently identical with the active hormone that has been isolated from the testes by Laqueur and his associates.¹ It is more potent than the androgen (male hormone), androsterone, which has been isolated from the urine. In preparing the drug it is now generally made as testosterone esters, and the propionate is now commonly employed, for it produces a more prolonged effect than does the simpler testosterone. These drugs must be injected parenterally though recently the use of an inunction has been introduced. Intramuscular doses are large and are commonly 10 to 25 mg. of the crystallized synthetic compound, injected as often as three times a week. While this is a large amount in endocrine therapy, it has at least a counterpart in the excretion rates. In normal individuals, both male and female, the ratio of urinary excretion of androgens to estrogens lies between 500:1 and 1000:1 in terms of weight so it is not surprising that similar ratio differences are found in the amounts necessary for therapeutic purposes.

It has long been well known that androgens are excreted in the urine of both males and females, and in fact in fairly high concentration. Recently, Nathanson, Towne and Aub have studied excretion in children and have found that even children of three years of age have a definite androgen excretion which gradually increases as puberty approaches. Boys, as well as men have a higher output than have females. However, there is no cyclic excretion of androgens as there is of estrogens, and therefore it is not necessary to do repeated observations in the study of the androgen excretion if this determination appears necessary before instituting therapy.

It must be remembered that though the effects of testosterone esters are apt to be striking, their

use is a pure substitution therapy just as is that of insulin. Testosterone does not stimulate the pituitary gland to greater activity in large doses, indeed, it appears to inhibit temporarily this important gland. The result is that testosterone does not stimulate the growth of the testes. It substitutes for the active secretion of that gland, and does this only so long as its injection is continued. McCullagh² has reported, and Nathanson's work³ confirms, that when testosterone is injected the androgens rise abruptly in the urine but return to their original level within forty-eight hours after the injection. But not all injected testosterone appears in the urine. What becomes of the remainder is not known. If a large dose of testosterone is given to individuals who are already excreting androgens after forty-eight hours the excretion level falls below the original level suggesting an inhibiting effect on the sex stimulating hormone of the pituitary gland.

When testosterone is injected into women the undesirable sequelae of hypertrichosis, enlargement of the clitoris and deepening of the voice may occur. The hypertrichosis may last for some months and has been said to remain even longer in old people. While these results have usually come only with the use of very large amounts of the drug, such changes have been observed with therapeutic doses. This possibility must be constantly borne in mind when the drug is employed in women. These undesirable effects of testosterone are described by Greenhill and Freed⁴ in 2 women who received 50 mg. every two or three days. They soon complained of increasing hair growth, and in one of them this was still present four months after the last injection. While this must be taken as a warning in regard to the use of testosterone, the amounts they received are probably larger than necessary for therapeutic effects.

Testosterone and its esters appear in my experience to be well tolerated, though their effects on the general feeling of patients may vary. Frequently patients respond with an increase of general vigor, though I have seen occasional responses of fatigue and lassitude. It is nearly impossible to dissociate these reactions from purely psychological responses to injections, but objective

evidences of the action of testosterone are obvious in many clinical conditions. The literature on this subject is rapidly enlarging, and though the following report is not based on a complete bibliography, it covers most of the important recent articles on the subject.

The Council on Pharmacy and Chemistry⁶ of the American Medical Association recently issued a most interesting and instructive report on the present status of testosterone, and decided not to include these preparations in its book *New and Non-Official Remedies* until the preparations had been properly evaluated by ample clinical experience. This decision was arrived at because of the varied claims made for the new drugs. It is obvious that a compound such as this needs careful evaluation before it can be recommended, and much exploratory work needs to be done before its applications in medicine will be well understood.

USE FOR HYPOGONADISM IN MALES

The best treatment for hypogonadism would be to stimulate the anterior pituitary gland to greater activity, and so indirectly stimulate the gonads. But a good technic for so stimulating the pituitary gland is not at hand. Thyroid medication does this to a moderate degree, but its effects are not dramatic. Substitution therapy for diminished anterior-pituitary activity, in the form of gonadotropic hormones, of anterior-pituitary-like hormone or of pregnant mare's serum concentrate, may have the effect of stimulating the growth of the testes temporarily, but it does not have the slow, prolonged influence of the pituitary gland itself. The anterior pituitary gland obviously has a very slow action. Nathanson, Towne and Aub² have shown its influence on androgen excretion as early as five years of age, with a gradual crescendo up to puberty. The gland therefore appears to have a prolonged stimulating effect, and similar sluggishness of effects should be expected from the physiological doses of substitution therapy. Of course, if larger doses are used, more rapid results are to be expected, though, like most effects of anterior-pituitary therapy, the active response may be of only a few weeks' duration.

The injection of testosterone or its esters has a more rapid effect, for this appears to be the activating hormone for the male secondary sex characteristics. Though it produces some of these effects in a period of weeks, it has no clear-cut stimulating effect on the testes themselves. There is, indeed, some evidence of a reverse effect, as judged by spermatozoa counts.

Hypogonadism in males demonstrates the most obvious effects of testosterone. McCullagh³ re-

cently published an excellent paper on the results of testosterone therapy in 6 cases of testicular deficiency at puberty. He showed that before treatment these patients excreted very little androgen in the urine, and that injected testosterone was promptly excreted, mostly within twenty-four hours. In cases of severe prepuberal hypogonadism he found that testosterone injections produced stimulation of all secondary sex characteristics in males, though prostate enlargement was the last to develop. The testicles did not seem to enlarge, but the number of spermatozoa did not decrease. The closing of bone epiphyses was not accelerated by testosterone—an observation of considerable significance in growing children.

McCullagh obtained good results in adult functional hypogonadism. In the adults treated by Nathanson and Aub,⁷ the results are equally striking. Erections and enlargement of the penis rapidly occur, followed by the growth of hair, changing of the voice and a moderate change in body configuration. The prostate enlarges to normal size as judged by palpation, whereas before treatment the gland could not be felt. Greater psychologic vigor and assurance are obvious, though these may well be purely psychologic responses to the physical changes.

Dunn⁸ confirms the stimulating effects on secondary sex characteristics, and also lays stress on the psychologic effects. He describes an improved mental concentration and interest in social activities, as well as improved physical energy and endurance.

The reports of Webster⁹ and of Eidelsberg and Ornstein¹⁰ are similar. The latter have administered testosterone for many months in the usual doses of 50 to 75 mg. per week. They have not observed a diminution in effect as the months go by, either in body changes or in an improved feeling of well-being and increased strength. Kearns¹¹ agrees as to the value of the drug when given intramuscularly, but also shows that it can be administered as an inunction in a greasy base. With the daily careful rubbing in of such an ointment, containing 4 mg., he obtained as satisfactory results as with injections. As proof of its absorption, he found increased androgen excretion in the urine.

All these dramatic effects appear to continue so long as testosterone therapy is maintained, and vary directly with the amount given. When therapy is stopped the eunuch returns in a period of weeks to his original state, though the deepened voice appears to be maintained.

It is to be expected that testosterone would be tried in many other conditions. Zehn¹² believes that daily 10-mg. injections of testosterone

constitute excellent treatment for benign hypertrophy of the prostate. This has also been reported by others, but not enough information has accumulated in regard to this difficult subject to warrant a conclusion as to its value.

USES IN FEMALES

Large doses of testosterone, like estrogens, apparently inhibit the production of sex-stimulating hormones by the pituitary gland so that uterine bleeding is inhibited. This results in an unstimulated ovary and hence a lack of secretion of ovarian hormones. Testosterone does not appear to have a depressing effect on the uterus itself¹³ in fact it exerts some stimulation directly even in ovariectomized females.¹⁴

The excellent result of the injection of testosterone at the menopause is a puzzling phenomenon, inasmuch as one would expect estrogens to be the drug indicated at that time. However, the work of Nathanson and Towne⁴ shows that in castrated women only a small quantity of injected testosterone is excreted in the urine as androgens. There is, on the contrary, a discernible increase in the total urinary estrogen output, and also a depressing effect on the pituitary gland, as evidenced by a decrease in the urinary follicle stimulating hormone. From its excretion products one must suspect that it is changed in part to estrogens. If one uses small, single doses, however, one may get other effects, as shown by Nathanson, Franseen and Sweeney¹⁵ in immature female rats. By the injection of a single dose of testosterone propionate there resulted a direct effect on the vagina, which produced a premature opening and an estrous response, as well as a direct effect on the uterus, and indeed an indirect stimulating effect on the ovary through stimulation of the anterior pituitary gland. It is the depressing effect on the pituitary gland of repeated doses that may account for the satisfactory effects it produces in the annoying symptoms of the menopause.

There is some evidence that testosterone also has an inhibiting effect on the peripheral female hormones, the estrogens. Thus Lipschütz¹⁶ has produced evidence that large doses of testosterone will inhibit the effect of Estradiol in castrated female guinea pigs, an effect characterized by an increase of weight, of musculature and of fibroids of the uterus. The use of testosterone propionate in the treatment of so-called essential dysmenorrhea, therefore, has some basis according to physiological knowledge. This type of pain, produced by contractions of the uterine musculature, seems relieved by the corpus-luteum hormone and intensified by estrone. Since testosterone appears an

antagonistic in some ways to estrone, there would seem to be some justification for its use in this syndrome. Rubinstein and Abarbanel¹⁷ found that it relieved most cases of essential, though it was not so helpful in anatomically determined, dysmenorrhea. Salmon, Geist and Walter¹⁸ also treated patients in this way. In 26 of 30 cases they obtained satisfactory results, and two thirds of the 25 cases followed for more than three months remained symptom-free. If 500 mg of testosterone propionate was given there was danger of hirsutism and change in voice, but the necessary dose is below this amount, and they recommend 250 to 350 mg., to be given during one cycle. They advance the theory that functional dysmenorrhea may be caused by an androgen deficiency.

Geist, Salmon and Gaines¹⁹ gave intramuscular injections of testosterone (300 to 1000 mg a month) for menorrhagia to patients who showed no gross evidence of disease. Bleeding stopped in 18 out of 20 cases, and uterine biopsies showed that this was usually accompanied by disappearance of the secretory phase, or even inhibition of the proliferative phase of the uterine endometrium. Menstruation, therefore, ceased, but within a month after stopping treatment the ovarian effects on the uterine mucosa again became evident and regular bleeding usually became re-established. These effects are again suggestive of the temporary inhibitory effect of testosterone on the sex stimulating hormones of the pituitary gland.

To 38 women with functional uterine bleeding, Mazer and Mazer²⁰ gave intramuscular injections of testosterone three times a week for from two to nine weeks. The total dosage per month ranged from 30 to 300 mg. A cure was considered to have occurred if the abnormal bleeding ceased and did not recur for at least four months after the discontinuance of treatment. By these criteria 68 per cent of the women were cured. It is interesting to note that the menstrual rhythm in the 30 patients who were menstruating regularly before the onset of the abnormal uterine bleeding was not disturbed.

MISCELLANEOUS USES

It would be natural to expect that testosterone with its suggestive antagonistic effects toward the estrogens would be effective in counteracting abnormal development of the breasts,²¹ and this should be particularly true in abnormal growth of the male breast. Hoffman²² tried such treatment in 28 males and found regression in 12 cases and a reduction of more than 75 per cent in 9 others, while in 2 cases there was complete failure. However, spontaneous regression occurred

in 3 untreated cases Wernicke²³ also tried this therapy in 4 cases, he obtained good results in 2, inasmuch as the gynecomastia disappeared, but there was a spontaneous recurrence in 1 case after therapy was stopped. On the other hand, Turner²⁴ did not find that testosterone influenced this condition in a man who had otherwise normal secondary sex development. It is important to remember that this disease improves spontaneously, and too much stress should not be laid, therefore, on improvement in a few cases. A larger amount of data is necessary before conclusions can be reached.

A more definite influence of testosterone on lactating breasts is indicated in a paper by Kurzkrok and O'Connell,²⁵ who treated 21 consecutive cases through early puerperiums in which lactation was considered undesirable. The patients were given repeated injections of testosterone propionate intramuscularly, usually in 25-mg doses twice a day until a total of 50 to 150 mg had been given. Only 2 of these 21 cases appeared to be treated unsuccessfully, and the symptoms associated with inhibition of lactation were relieved within twenty-four hours without the addition of any other therapeutic measures. As soon as complete relief of symptoms was obtained hormone injections were stopped, and no unpleasant aftereffects were observed.

This work has been confirmed by Beilly and Solomon,²⁶ who treated 108 consecutive postpartum cases with testosterone propionate. They obtained optimal results in 58 per cent and a lessening of milk production in 40 per cent, and the effectiveness did not seem to be related to the postpartum date of beginning treatment. They also found no deleterious effects from therapy, and no obvious breast-tissue changes were observed.

The use of testosterone propionate in the treatment of chronic mastitis was described by Spence.²⁷ He reports a relief of pain in 14 of 16 cases, and a reduction of the nodules in the breasts of two thirds of his patients. He used quite large doses of the drug and described, unfortunately, increased hirsutism in several young patients.

That testosterone will improve eczemas and psoriasis in women with menstrual disorders and in some men is asserted by Lafitte and Huret.²⁸

Arndt²⁹ claims that testosterone will give a prolonged improvement in patients with neurasthenia and in men suffering from intermittent claudication, even with early gangrene, and from angina pectoris. That about twelve injections of testosterone greatly improved—and indeed cured—many of the severe psychoses associated with the menopause is claimed by Weiss.³⁰

SUMMARY

From this report of the practical use of testosterone in clinical medicine it is obvious that the drug is a potent one, particularly in hypogonadism in males. In this condition its effectiveness as substitution therapy is uniformly accepted. For other diseases for which it has been recommended more careful observation is essential before definite conclusions can be reached. The evidence for its effectiveness in prostatic hypertrophy varies. Its use in females is the more interesting development of the last year or two, and at the menopause often seems to be even more effective in controlling vasomotor difficulties than are the estrogens. Its value in dysmenorrhea and abnormal bleeding is asserted, but needs further confirmation, and its help in drying up postpartum breast secretion has been confirmed with a reasonably large series of cases. It is therefore likely that in the next several years the use of testosterone for various abnormalities will become better established. This is not surprising, inasmuch as androgens are actively secreted, in both men and women, and probably purely by their antagonism to estrogens play an important role in hormonal control of the menstrual cycles. Of all the recent endocrine drugs, testosterone and its esters are at the moment the most interesting, as is well attested by the enormous number of publications appearing in regard to their use.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26211

PRESENTATION OF CASE

First Admission A fifty-seven-year-old Swedish cook was admitted to the hospital complaining of indigestion of some ten years' duration.

For ten years the patient had experienced transient, recurrent, increasingly frequent attacks of indigestion, associated with cramp-like pain in the epigastrium and right upper quadrant of the abdomen, often radiating to the right hypochondrium and mid-back. These attacks were precipitated by the ingestion of greasy or fatty foods and were accompanied by nausea, vomiting and a feeling of epigastric fullness with flatus. No jaundice, constipation, diarrhea, chills, fever, clay-colored stools, or dark urine was noticed until the last episode, the morning of admission to the hospital, when she ate a breakfast consisting of an egg, toast, butter and coffee with cream. A few minutes later a typical, severe attack ensued. However, the upper and right abdominal pain failed to remit with the usual remedy, namely, baking soda. At noon that day she experienced a severe shaking chill, which lasted thirty minutes. Because of these complaints she was brought to the hospital for treatment. The past and family histories were non-contributory. The menopause had occurred five to six years before admission. She had had no hot flashes, but had had two menstrual periods since that time, the last occurring eighteen months before admission. A uterine suspension with appendectomy was performed in an outside hospital twenty years before admission.

Physical examination revealed an obese, slightly pale woman who complained of pain in the right upper abdominal quadrant, where there was also localized tenderness with slight muscle spasm. No abdominal or pelvic masses were palpated. The remainder of the physical examination was essentially normal.

The temperature was 101°F, the pulse 108, and the respirations 28.

Examination of the blood showed a red-cell count of 3,500,000 with a hemoglobin of 90 per cent (Tallqvist), and a white-cell count of 13,000 with 75 per cent polymorphonuclears. The urine was negative, no bile being present. Stools were soft, formed and dark brown. The blood Hin-

ton test was negative. The van den Bergh test was 6.67 mg per 100 cc., with a biphasic reaction.

The temperature, pulse and respirations fell to normal levels on the day after admission, and except for slight jaundice which appeared and soon vanished, the patient's symptoms improved steadily. She developed a mild upper-respiratory infection, and on the seventh hospital day, when the latter had subsided, a laparotomy was performed under general anesthesia. On exploration of the abdomen the tubes and ovaries were normal to palpation. The uterus was found to have been suspended at the previous operation, but had remained adherent only on the right side. Exploration of the cecum revealed that the appendix had been removed at the previous operation. There were a moderate number of adhesions about the gall bladder, but no very marked signs of inflammation. This organ was removed, and the common duct was explored and drained. Many pigmented stones of various sizes were found in the gall bladder and common bile duct.

The patient enjoyed an uneventful postoperative course, and was discharged on the thirteenth postoperative day.

Final Admission (six months later) Following discharge from the hospital, the patient improved steadily and satisfactorily, but never quite regained her normal vigor. Approximately two months before the second admission she began to experience, for the first time, dull, aching pains in the right lower abdomen. These came and went, lasted a few minutes to an hour or two and recurred irregularly one to four times a day for a week or more at a time. The discomfort caused her little distress as it was never so severe as the pains she had experienced before the cholecystectomy was performed. About one month before admission she began to notice attacks of "indigestion," characterized by ill-described but apparently severe pain in the epigastrium, which radiated around the torso to the right back and sometimes to the left hypochondrium. These episodes usually occurred in the midafternoon and again in the early morning hours, and became so frequent that they were a daily occurrence. Relief from the discomfort was obtained by massaging the abdomen until vomiting followed. The vomitus was usually sour, rarely bitter, and at no time contained evidence of fresh blood. She became anorexic, noted increasing fatigue and torpor, and complained of constipation and gas, which were relieved only by oil or cathartics. She had lost about 6 pounds during the month before re-entry. She continued to work until two days before admission.

Physical examination showed a firm, tender, smooth, rounded mass, measuring about 10 cm in diameter, in the right lower quadrant. It shifted with respiration and by palpation in a cephalad or caudad direction, and was definitely outlined by the examining hand.

The temperature, pulse and respirations were normal.

The blood showed a red-cell count of 4,340,000 with 13.6 gm hemoglobin (photoelectric-cell technique), and a white-cell count of 7500 with 58 per cent polymorphonuclears. The urine was negative. The stools were brown, soft, formed and guaiac positive.

A barium enema passed to a point just above the cecum that corresponded to the upper border of the palpable abdominal mass. At this point a temporary delay was noted, and the barium was seen to pass suddenly into the cecum and ileum. A rounded mass was seen projecting upward into the ascending colon, and the ileum lay in the center of this mass. The ileum was slightly dilated, its margins were irregular, and there was complete absence of the mucosal markings. There also appeared to be destruction of the colonic markings around the ileocecal valve. The cecum was reduced to a small crescentic cavity lying along the lateral margin of the mass. After evacuation the appearance was much the same except that the upper margin of the mass projecting into the colon was better demonstrated. Filling the colon with air gave no additional information.

On the sixth hospital day, an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JAMES E. FISH The question immediately arises in a situation of this sort as to whether the secondary condition which brought about the re-entry co-existed at the time of the original entry, or whether it developed as a complication of the first condition or perhaps as a complication of the operation. A mass appearing in the abdomen a matter of months following an abdominal operation, of course, makes us think of the possibility, even though we do not believe it is likely, of a sponge that had been left in the abdomen. We can assume that the "sponge count" was correct. Furthermore, the sponges at the Massachusetts General Hospital have attached to them a metal clip, hence, a sponge in the abdomen would show immediately on x-ray examination with a flat plate. Furthermore, the mass described by x-ray does not suggest that sort of complication. So I think we can rule out any such possibility as a cause for this mass in the right lower quadrant.

In summary of this rather long history, I am

inclined to believe the first episode was a clear-cut attack of choledocholithiasis. The fever and chill in the absence of more marked evidence of inflammation in the gall bladder are undoubtedly accounted for by some slight degree of liver involvement—a cholangitis. She had a severe chill on the first admission to the hospital, and a van den Bergh that might suggest liver damage. The finding at operation of small stones in the common duct as well as in the gall bladder is certainly in keeping with such an assumption. It therefore seems proper to discard the first operation as having any direct relation to this second episode. The first operation, therefore, becomes of interest to us only from the point of view of knowing whether the cecum was perfectly normal at the time of the abdominal exploration or whether some lesion was present but overlooked.

Let us run through some of the symptoms. We notice that the patient did very well for four months—another fact that certainly is against any complication from the operation. Then after four months she began for the first time, to have dull aching pain in the right lower abdomen. This came and went. It is not described exactly as peristaltic pain, and yet it does suggest that type of pain. A little farther on we get additional information about the pain, namely, that it was severe in the epigastrium and that it radiated around to the back and sometimes to the left hypochondrium. The pain is not exactly typical of small-bowel pain but certainly is not inconsistent with it in the presence of partial or intermittent obstruction. I can attach no significance to the fact that the pain occurred in the midafternoon or early morning hours. There was a progressive factor in that the pain became more and more frequent until it was a daily occurrence. The patient obtained relief by massaging the abdomen. That is an extraordinary observation, if correct, and it would seem to fit into the ultimate picture. Whether she obtained relief by the vomiting that followed or whether she in some way displaced the tumor mass in the abdomen by massage is not clear. I cannot attach any particular significance to the type of vomitus. We now note the presence of constipation and gas. These additional symptoms plus nausea and vomiting are common symptoms of intestinal obstruction, even in a mild degree. She lost some weight,—6 pounds during the month before admission,—and yet with all this partial intestinal obstruction the individual was well enough between episodes so that she continued to work," confirming the impression that her difficulties were due to partial and intermittent obstruction.

On physical examination she had a fairly sized

ble tumor—the size of a man's fist, it shifted with respiration and, still more important, it shifted in an up-and-down direction on palpation. Apparently it did not shift laterally very much. That would suggest that it was in the cecum, since the cecum, being tied down unlike the small intestine with its longer mesentery, might only move up and down in this manner. If it were a mass in the small intestine it would move more freely in all directions. Furthermore, the lack of more pronounced fixation would suggest that the tumor was not retroperitoneal. We note further that the temperature, pulse and respirations were normal and that the white count was fairly low. This is all very strong evidence against the presence of an inflammatory mass. The positive guaiac test is important, but not especially diagnostic. It suggests, certainly, an erosion or break in the lining of the mucous membrane, but we do note positive guaiac tests in the stools even with inflammatory processes outside the bowel wall. I even remember positive guaiac tests in several cases of appendiceal abscess. From the description of the barium enema we certainly get the impression that the mass surrounded the end of the ileum projecting into the bowel and that brings to my mind particularly the thought of an intussusception of the ileum into the cecum. A little farther along we note that the mucosal markings in the terminal ileum were absent. That would suggest some sort of an infiltrating process, neoplastic or inflammatory, that had eradicated those markings. The description of the mucous membrane that was noted in the x-ray examination in the cecum is further evidence but does not help in the differentiation between an inflammatory and a neoplastic process.

Are the x-ray films available?

DR. AUBREY O. HAMPTON: The question of a sponge was raised and plain films were taken, but they do not show a clip such as the Massachusetts General Hospital sponges contain. Furthermore, no dilated loops of small bowel were seen, nor was there other evidence of obstruction. The film taken at the time of the barium enema shows a rather unusual picture, this being the cecum and this the terminal ileum. The terminal ileum shows definite ulceration, which ends abruptly at the margin of the mass. This smooth concave margin of the cecum represents the point of invagination into the cecum, and the mucosal folds in this area appear normal. The point at which we suspected destruction of the mucosal folds is immediately around the ileocecal valve. The abrupt ending of the process would probably help rule out ileitis or tuberculosis.

DR. FISH: It seems to me that we have a good

deal of evidence against an inflammatory process, and I might say further that a primary intussusception would hardly be considered in this situation. In the first place, for an adult to have primary intussusception is an extraordinarily rare phenomenon, and the intussusceptions that do occur are more apt to be of a type associated with chronic and intermittent low grade obstruction of this sort. The primary lesion leading to the intussusception might be inflammatory, such as regional ileitis or tuberculosis. However, in inflammatory lesions of the ileum rarely are the cause of intussusception. That leaves us with the conclusion that the primary process must have been neoplastic. Of the possible neoplastic conditions we might mention a benign neoplasm of the small bowel, but the length of involvement of the ileum is distinctly against that sort of thing. I think carcinoma is unlikely, and it seems to me that the diagnosis boils down to a lymphoma with secondary intussusception of the terminal ileum into the cecum.

DR. WILLIAM B. BREED: What about the possibility of a benign polyp associated with intussusception?

DR. FISH: I am of the opinion that such was probably not the case, in view of Dr. Hampton's statement regarding destruction of the mucosal markings over such a length of terminal ileum.

DR. HENRY H. FAXON: There are three points of interest to bring out. In the first place, the gall-bladder incident is of interest only as it gave a chance to see what the cecum was like a relatively short time before the terminal illness. At the first operation I exposed the cecum, and am sure that nothing abnormal was present on palpation or inspection.

Secondly, the history is misleading in that it lays a good deal more emphasis on the symptom of pain than was brought out when she first came to see me. The chief thing that bothered her was the lump in the side that she herself had discovered.

The third point is that it was surprising, after the true state of affairs had been found out, she did not have more in the way of obstructive symptoms. At operation it was discovered that a large segment of the terminal ileum had intussuscepted into the cecum. Adherent to it, not by inflammatory reaction but by actual invasion of the growth, were loops of small intestine. A first stage ileotransverse colostomy was done, and I was later able to resect the right colon and small intestine en masse. She did well immediately following operation but then developed intestinal obstruction and a fecal fistula and finally died.

about ten weeks after operation, primarily from inanition because I was unable, even at a third attempt, to isolate and close this fistula.

PREOPERATIVE DIAGNOSIS

Malignant lymphoma of terminal ileum

DR. FISH'S DIAGNOSES

Lymphoma of terminal ileum
Secondary intussusception into cecum

ANATOMIC DIAGNOSIS

Reticulum-cell sarcoma of ileum

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY The differential diagnosis here was essentially that of a neoplasm that would develop as rapidly as this, assuming that the first exploration was adequate, and I think we can safely assume there was no tumor present at that time. Five months later there was a tumor of sufficient size so that the patient could feel it herself. The microscopic examination shows that it was a form of lymphoma which we classify as reticulum-cell sarcoma, a rather frequent type of lymphoma to be found in the bowel. The primary tumor was apparently in the ileum which was most extensively involved. Besides the intussusception there was considerable neoplastic invasion of the cecum, as well as some involvement of another loop of small bowel, so a very extensive operation was necessary.

DR. MAURICE FREMONT-SMITH There was no evidence of reticulum-cell sarcoma elsewhere?

DR. MALLORY No.

DR. J. H. MEANS Was it an annular growth?

DR. MALLORY Yes.

One question came up a few months ago in a similar case of intussusception of the ileum into the cecum. Dr. John Homans was present at the conference, and I asked him if he had ever seen intussusception in a case of regional ileitis. He said he had not. That is also our experience. We have found it quite common in association with tumors but extremely rare in association with inflammatory lesions.

DR. HAMPTON Another important point in differential diagnosis which I failed to mention was that the ileum at the site of the disease was larger than normal. In cases of regional ileitis it is small.

DR. FREMONT-SMITH Was the patient too old for a regional ileitis to occur?

DR. MALLORY I do not believe I have seen ileitis this late in life.

CASE 26212

PRESENTATION OF CASE

A thirty six year-old American housewife entered complaining of shortness of breath and edema.

Approximately two and a half years before admission the patient began to notice increased breathlessness on exertion especially after climbing stairs. This dyspnea increased progressively until admission so that she could walk only about five or ten yards on the level without becoming markedly out of breath. It had been especially marked during the past year. She stated that very often "everything went black" after the slightest exertion. Four months before entry her ankles began to become swollen toward the end of the day, but the swelling disappeared after a night's rest. During the two weeks prior to entry the swelling had become much more marked, especially on the right. During this four month period she had been in bed practically all the time. One month before entry she noticed a swelling over the lumbar region, which appeared after she had been propped up in bed for some time. It disappeared when she lay down and reappeared when she was propped up again. Three months before admission she had had an attack of tachycardia which lasted from 6 a.m. to 1.30 p.m. and during which she had to fight for breath. Since then she had had two or three similar attacks of a milder nature, the last one occurring about one week before entry. During the month before entry her abdomen had become distended and she felt uncomfortable when she lay on her left side. She had also had nausea and occasional vomiting. During the previous two months she had been using two pillows. Since the onset of the shortness of breath two and a half years before she had had a dry, hacking, unproductive cough especially following exertion. This had not changed in character.

The family history was noncontributory.

She had been married eleven years. The husband was living and well. Her first pregnancy which had occurred ten years before entry, terminated at seven months as a result of toxemia. Two years later she had had a miscarriage at three months, and two years after that another child had died as a result of toxemia during the eighth month. Curettages had been performed four and two years before entry.

She had the usual childhood diseases. There was no history of pneumonia, pleurisy or rheumatic fever. There had been no contact with tuberculosis. She had had several severe sore throats before the age of twenty five, and a tonsillectomy had been performed twice. Since then she had had no sore throats.

Physical examination showed a rather thin but fairly well-developed woman sitting propped up in bed and having a little difficulty in breathing and an occasional dry cough. The lips and fingertips were slightly cyanotic. The left fundus showed a bluish-gray rim about the nerve head, slightly suggesting a partial separation of the retina. The heart was greatly enlarged. The maximum apical impulse was felt 14 cm to the left of the midsternal line in the fifth interspace, 6 cm beyond the midclavicular line. There was no heave of the precordium, and no thrill was palpable. The sounds were loud and of good quality. The rhythm was regular. The pulmonic second sound was greater than the aortic. There was a low-pitched diastolic rumble extending through diastole and ending in a crescendo in the first sound at the apex, best heard in the axilla. A high-pitched short systolic blow and a soft systolic blow were heard over the base. The pulses were equal and of small volume. The neck veins were moderately engorged and showed visible pulsations. The blood pressure on the right was 106 systolic, 92 diastolic, and on the left 126 systolic, 118 diastolic. The chest showed dullness at both bases, with moist rales extending to the midclavicular regions. The liver was felt 9 cm below the costal margin in the right midclavicular line, and was firm and tender. The abdomen was distended, and dull in the flanks, and a fluid wave could be demonstrated. The veins were prominent. The tip of the spleen could barely be felt. There was slight pitting edema of the feet and shins, and moderate edema of the sacrum.

The temperature was 98°F, the pulse 72, and the respirations 22.

The urine showed a specific gravity of 1.008 to 1.010, a slight trace of albumin and a sediment which contained an occasional white blood cell. The blood showed a red-cell count of 5,190,000 with a hemoglobin of 85 per cent, and a white-cell count of 13,000 with 78 per cent polymorphonuclears. The stools and sputum were normal. The venous pressure in the right arm by the direct method was 18 cm. The nonprotein nitrogen of the blood was 50 mg per 100 cc, the serum protein 6.2 gm.

X-ray examination of the chest showed that both sides of the diaphragm were obscured by homogeneous dullness which rose in the axillary line to about the middle of the scapula. The heart shadow was difficult to outline, but the heart was enlarged both to the right and to the left. The upper left and right borders were unusually prominent. The blood vessels of the lung were large. There was extension of the dullness at the right base into the region of the interlobar pleura.

On the second day the blood pressure in the left arm was 105 systolic, 95 diastolic, and in the right, 110 systolic, 90 diastolic. Further observation showed that the heart apparently shifted several centimeters with changes from the left lateral to the right lateral position. The liver edge was felt 12 cm below the ensiform and the same distance below the right costal border in the nipple line. There was no Broadbent sign. The patient was given 1½ gr of digitalis three times a day. The fluid intake was limited to 1200 cc daily. She was also given Salyrgan, without appreciable effect. She continued to cough considerably, and there was an acetone odor to the breath. Southey tubes were inserted for nine and a half hours on the twelfth day. Approximately 2000 cc of fluid was removed. The tubes were used again about one month after entry. During the fifth week she gradually became drowsy, developed increasing pallor and showed distinctly icteric sclerae. On the fortieth day, after a visit from her husband, she suddenly gasped and died in a few minutes.

DIFFERENTIAL DIAGNOSIS

DR J SYDNEY STILLMAN. It seems clear that we are dealing here with a patient who died from heart failure. The problem is to determine as accurately as possible the nature of the pathologic changes which led to it.

The patient's history before the onset of the present illness gives some leads, but that is all. She had had two attacks of toxemia of pregnancy, leading to premature delivery in the first pregnancy and a dead baby at eight months in the third. The second pregnancy resulted in a miscarriage at three months, too early for the onset of toxemia. Two curettages, which I assume to have been therapeutic abortions, were done thereafter. The attacks of toxemia might well have led to the development of hypertension and hypertensive heart disease.

The patient had "several severe sore throats" before the age of twenty-five, apparently severe enough to lead to two tonsillectomies. There is no history of rheumatic fever, but only too frequently one finds rheumatic valvular disease without a definite history of an active rheumatic process.

The final illness began two and a half years before entry and consisted essentially of a slow, steady, progressive failure of the left heart for a little over two years, then, four months before entry, right-sided failure began. In spite of bed rest, digitalis, diuretics, restriction of fluids and Southey tubes the patient failed to rally and died on the fortieth hospital day. Unfortunately, we are not given the help of blood-pressure determi-

nations or auscultatory examinations of the heart previous to admission to the hospital.

Physical examination revealed slight orthopnea, cyanosis of the fingers and lips and an occasional dry cough. There was a suggestion of a partial separation of the left retina, probably a scar of the toxemia of pregnancy. The heart was greatly enlarged. The sounds were loud and of good quality. The rhythm was regular. The murmurs of mitral stenosis and regurgitation were present. There is a meager description of a systolic murmur at the base. The pulse pressure and systolic pressure were low, with the diastolic pressure elevated or high normal. The signs of hydrothorax and pulmonary edema are evidence of left-sided heart failure, and the cyanosis, engorged neck veins, enlarged liver and spleen, ascites and peripheral edema show marked right-sided failure.

A diagnosis of rheumatic valvular disease with mitral stenosis and regurgitation seems justified. It is hard to evaluate the systolic murmur at the base. Although it might well be caused by a slight degree of aortic stenosis, which would be supported by the decrease in intensity of the aortic second sound, it seems quite likely that it was due to a dilatation of the heart and was really a functional murmur. It does not seem necessary to have had tricuspid stenosis to account for the findings in this case, and against it are the lack of the characteristic murmurs and of pulsation of the liver. Although a subacute or chronic active rheumatic disease would lead to the relentless course this patient ran, there is no evidence to point to its existence.

Because of the marked degree of obstruction to the return of blood to the heart, the low blood and pulse pressures and the progressive course without response to the usually effective means of therapy, adhesive pericarditis must be considered. It is obvious from the statements about the shift in position of the heart with changes in position and the absence of Broadbent's sign that this diagnosis was considered by the visiting staff. In addition to the two findings just noted there are other features which make this diagnosis unlikely. First, if one accepts the diagnosis of rheumatic valvular disease, which seems advisable, the diagnosis of adhesive pericarditis is unlikely. In 15 cases of the disease reported by Dr. Paul D. White¹ and 19 cases reported by Dr. C. Sidney Burwell² there was no evidence that associated rheumatic heart disease or rheumatic fever played a part in the etiology. In 1000 cases of rheumatic heart disease followed at the House of the Good Samaritan there were no cases of adhesive pericarditis. Furthermore, if one does not accept the diagnosis

of rheumatic mitral disease one cannot explain all the murmurs. Second, the heart was larger than that found with adhesive pericarditis. Third, there was no evidence of tuberculosis, a common cause.

One must consider the possibility of hypertensive heart disease, either acting as the single cause of this patient's death or existing in conjunction with rheumatic valvular disease. The first possibility seems unlikely because of the presence of an apical diastolic murmur, the extremely large heart, the absence of any abnormally high blood pressure reading or the history of one, the absence of vascular changes in the ocular fundi, the two-year history of progressive left-sided heart failure before the right side failed and the degree of venous obstruction.

Is it possible that the patient developed hypertension six to ten years before entry—that is, after the toxemia? It seems quite likely because she developed toxemia in the two pregnancies that lasted into the third trimester. Furthermore, Fishberg³ says that essential hypertension develops with remarkable frequency in middle-aged women with mitral stenosis. It is possible that hypertension existed in this patient until a dilatation of the heart occurred and that the latter contributed to the marked degree of congestive failure. The high diastolic pressure and low specific gravity of the urine, with a slight trace of albumin favor this hypothesis. However, a fall of pressure from an abnormally high level to an abnormally low one would seem more likely to have been a terminal event. The combination of mitral stenosis and hypertension frequently leads to auricular fibrillation, which this patient did not have unless the attacks of transient tachycardia were caused by paroxysmal auricular fibrillation. Furthermore, the association of these two conditions does not seem unfavorable.

In summary, I believe that this patient had rheumatic heart disease with mitral stenosis and regurgitation and possibly a slight degree of aortic stenosis. Pathologically, I should expect to find some changes in the kidneys and arterioles suggestive of essential hypertension. However, I do not believe that essential hypertension played more than a supporting role in this patient's illness. The jaundice terminally I believe, was due to chronic passive congestion and central necrosis of the liver. I doubt the existence of true cardiac cirrhosis.

CLINICAL DIAGNOSES

Rheumatic heart disease, with mitral stenosis.
Cardiac decompensation
Cardiac hypertrophy

DR. STILLMAN'S DIAGNOSES

Rheumatic heart disease, with mitral stenosis and regurgitation
 Aortic stenosis, slight?
 Congestive heart failure
 Chronic passive congestion of the liver, with central necrosis
 Arteriolar sclerosis

ANATOMIC DIAGNOSES

Endocarditis, chronic rheumatic, with stenosis, mitral
 Cardiac hypertrophy, rheumatic
 Pulmonary embolus, right
 Pulmonary infarct, right lower and middle lobes
 Bronchopneumonia, right, slight
 Hydrothorax right, marked, left, slight

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY I should like to start by apologizing to Dr Stillman for what I believe is a serious omission from the abstract of this patient's record. The initial temperature was as reported, 98°F, and subsequent recordings for the next five days ranged from 96 to 98 by mouth. As soon as a shift was made to rectal temperatures, however, it was discovered that the figures ranged constantly between 100 and 101°F, with occasional spikes to 102. She did, therefore, have a low-grade fever accompanying the leukocytosis.

Dr Stillman was, of course, correct in his primary diagnosis of rheumatic heart disease with mitral stenosis and regurgitation. The valve leaflets were markedly thickened and interadherent, and the cords so shortened that the apices of the papillary muscles were virtually in contact with the valve margins. The other valves were negative. The heart was markedly enlarged, showing moderate hypertrophy and great dilatation of both auricles and of the right ventricle. In fact the pulmonary conus was in itself almost as large as the left ventricle. Despite the marked dilatation of the right ventricle, its wall measured 8 mm in thickness.

This, however, was not all the story. The right pleural cavity showed, as the x-ray film suggested, a considerable amount of fluid, just under 1000 cc. In addition, however, there were two very large

pulmonary infarcts, one occupying two thirds of the lower lobe, and the other almost all the middle lobe. In the corresponding branches of the pulmonary artery were grayish-red, firmly adherent thrombi, which had evidently been present for a period of some weeks. Microscopic examination of the pulmonary infarct showed a marked leukocytic reaction and beginning encapsulation at the periphery, suggesting a duration of approximately a month. Sections of lung tissue outside the areas of infarction showed considerable thickening of the small pulmonary arterioles of the type frequently seen in mitral stenosis. From the anatomical point of view the degree of cor pulmonale was greater than that which mitral stenosis alone would explain, a finding suggestive of considerable resistance within the pulmonary arterial tree itself.

We are constantly becoming more aware of the importance of pulmonary embolism in cardiac patients. Dr White has recently called our attention to the fact that decompensation alone is not an adequate cause for fever or leukocytosis. Unsuspected pulmonary infarction is one of the factors which can frequently be shown to be responsible for such a reaction. In the diagnosis of pulmonary embolism we always lean heavily on the x-ray examination. It is worth remembering, however, that, as in this case, an accumulation of fluid may make x-ray diagnosis difficult or impossible and Hampton and Castleman⁴ have shown that pleural effusion not infrequently accompanies pulmonary embolism and infarction. One point which justifiably might have aroused Dr Stillman's suspicion was the appearance of jaundice. It is quite true that it can be explained purely on the basis of passive congestion of the liver, but it is much commoner in association with large pulmonary infarcts. Unfortunately the postmortem examination was restricted, and therefore I cannot report on the kidneys. In view of the repeated toxemias, it would have been extremely interesting to have examined them.

LODGE MEDICAL BILL

On March 19, Senator Henry Cabot Lodge introduced a bill (S 3630) to amend the Social Security Act. The first part of this bill provides for the furnishing of funds up to \$40 per year for medical, dental and hospital services to unemployed persons who are receiving unemployment insurance benefits or to members of the families of such persons. It specifies that services of any legally practicing physician or dentist to eligible people shall be paid for, but in the case of hospitals makes a distinction between "profit" and "non profit" institutions. A result would be that, in the case of a doctor owning a hospital and practicing in it, the doctor could be paid for his professional services, but not for the services of his hospital. Whether this is a proper distinction, or an important one need not be discussed. The second

part of the bill provides funds for the states to match and expend, through suitable organizations, for the purpose of furnishing x-ray treatment, respirators and certain drugs, hormones, vitamins and vaccines for the indigent. In connection with this section several parts merit discussion.

As is obvious from Senator Lodge's discussion of his bill (*Congressional Record* 86 4702-4705, 1940), he intends that the bill provide for x-ray examination rather than x-ray treatment. He stresses that many poor people need x-ray examinations early in some illnesses, but do not secure them because of the cost. The problems that arise because x-ray examinations rather than other medical examinations are to be furnished seem interesting. Theoretically and practically the section of the public that is eligible for this aid will tend to go to the roentgenologist rather than to the general doctor, and there will be a great tendency for people to demand x-ray examinations that any doctor knows would have very little or even no chance of showing information of value to the patient.

In regard to the furnishing of drugs, Senator Lodge wants to provide especially the more expensive medicines such as insulin which perhaps are not always available to poor people in certain areas. As a matter of fact a leading medical social worker in Boston has stated that her department has a very difficult time getting various welfare departments to furnish liver extract insulin and so forth to many recipients of aid who need such drugs to maintain life. In the case of people not on relief rolls there is no way of obtaining such medicines except through their own efforts or the aid of private charity. This is an attempt to solve a relief problem that is theoretically correctable by intelligent administration to each local relief organization. That such provisions should be needed in any part of the country is somewhat of a reflection on these organizations.

An interesting feature of the bill is that it would take money from social security funds and use it in the care of the indigent without regard to whether the individuals benefiting had ever contributed to the funds. Inasmuch as the social-

security funds are raised by a tax on the wages of workers and a pay-roll tax on their employers for the purpose of providing for the former in their old age, it is questionable how much of this money should be diverted to other purposes (Such diversions are not new, but whether they are justifiable is a moot point) If local medical care of the unemployed and indigent needs financial support from the Federal Government, and many people think it does, would it not be better to face the fact frankly and appropriate money raised by general taxes rather than take money from social-security levies? This bill in final analysis would put the Federal Government into the field of curative medicine. It would do something to alleviate two situations that have arisen only where and because local medical care for the unemployed and indigent has been either inefficient or absent. Although it is in no way comparable in size and in method of administration with the Wagner Bill, it is like the latter in taking into the province of federal administration what has always been a local function.

Why are such bills introduced? Some lay the blame to a large extent on the members of the medical profession. Who, better than they, should know the difficulties the poor have in getting good medical care and in buying lifesaving medicines? But, on the other hand, just how much has each doctor done to secure humane, efficient poor laws, to ensure the election of intelligent, honest local governments and the appointment of proper administrators and employees in welfare departments and to inform welfare departments in regard to proper methods and policies in providing the medical aspects of relief for the indigent? More individual effort along these lines is desirable and would do much in correcting a state of affairs that is at least partly responsible for the public clamor for "state medicine."

MILITARY MEDICINE

TRAUMA as a cause of disability is constantly growing more important with the increasing mechanization of civilization, and the surgical treatment of injury produced by physical agents is a

vital factor in modern medicine. Such injuries often concern young vigorous adults not formerly a large group in the doctor's consulting room. Furthermore, the physician's activities are more and more concerned with youth and old age, and he meets those in the former group primarily for prophylactic measures against diseases that many younger physicians have only rarely seen. At no period in the world's history has medical practice so closely approximated conditions and problems formerly seen only in war time. An unusual number of articles on the treatment of individuals in the mass are written. As general health and prophylactic measures increase in number, the practicing physician is forced in increasing degree to consider problems highly similar to those of the military surgeon.

Opportunities for the study of traumatic surgery and mass public-health measures are available in highly specialized courses. Rarely are short summaries of recent advances and modern attitudes in these fields available to the practitioner of medicine. Such a course is now available in the curriculum of the Courses for Graduates at the Harvard Medical School as the course "Military Medicine and Surgery." It is open to all medical reserve officers of the United States Army and provides professional information in just those fields which are difficult for the practitioner to cover in a short time by any other means.

It is evident that the value of a well trained medical personnel is highly important to every country. The balance of international politics is so precarious that anything may happen. Isolation from the present conflict unfortunately is not accompanied by insulation, and despite overwhelming desires, this country may become involved. If this becomes the case, it seems inevitable that a considerable military effort will be the result. Even now, the modest expansion of the Army has produced calls for reserve personnel. For doctors who hold commissions as reserve officers it becomes their duty to themselves and to the profession they represent to be, at all times, prepared for immediate efficient professional service, and for this purpose, courses such as the one here mentioned

are being conducted at various places throughout the country

The course at the Harvard Medical School will be given during the first two weeks in June. A concise and up-to-date consideration of general problems in medicine and surgery—with particular emphasis on preventive measures, treatment and trauma—cannot fail to be advantageous. The development in these fields is sufficiently rapid to make it almost mandatory for the practitioner of medicine who is a reserve officer to take advantage of the opportunity to secure valuable postgraduate instruction.

MEDICAL EPONYM

BRODIE'S ABSCESS

Brodie's original description of the abscess bearing his name was published in 1838 or possibly somewhat later. The following quotation is taken from pages 395-411, "On Chronic Abscesses of the Tibia," in a volume, *Lectures Illustrative of Various Subjects in Pathology and Surgery* (London: Longman, Brown, Green and Longmans, 1846) by Sir Benjamin C. Brodie (1783-1862), sergeant surgeon to the Queen. These lectures were given to the students of St. George's Hospital.

When the tibia is enlarged from a deposit of bone externally when there is excessive pain such as may be supposed to depend on extreme tension the pain being aggravated at intervals, and these symptoms continue and become still further aggravated, not yielding to medicines, or other treatment that may be had recourse to, then you may reasonably suspect the existence of abscess in the centre of the bone.

MASSACHUSETTS MEDICAL SOCIETY

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., Secretary
330 Dartmouth Street
Boston

PYELITIS OF PREGNANCY

Mrs. C. M., a twenty-five-year-old primipara, when six months pregnant, entered the hospital on September 3, 1935, with a history of right-sided pain on and off for a month and a half, associated during the previous two weeks with oc-

casional chills and fever, urgency, frequency and dysuria. She had had six days of conservative treatment in another hospital without noticeable effect.

The family history was irrelevant. The patient's past history was non-contributory. Catamenia began at fourteen, were regular with a twenty-eight-day cycle and lasted four days without discomfort. Her last period was March 1, making the expected date of confinement December 8.

Physical examination on admission showed a well-developed and well-nourished young woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. There was marked tenderness over the right kidney. The uterus was enlarged to a size consistent with the period of amenorrhea and the fetal heart was present. A urine sediment showed large numbers of white blood cells in clumps, but no casts or red cells. A culture showed *Bacillus coli*. A blood examination on September 3 showed the hemoglobin to be 65 per cent, the red-cell count 3,920,000, and the white-cell count 24,200. A diagnosis of pyelitis was made.

On September 6 the temperature rose to 104°F. The treatment was supportive and symptomatic for nine days, but as it was thought that this treatment was of no avail and as a white-cell count on September 12 was 16,400, a cystoscopy was performed. As the urine from the right ureter contained many leukocytes, the right renal pelvis was irrigated with boric acid solution. A ureteral catheter was left in situ until September 15, when the temperature was normal.

The patient was discharged on September 21, asymptomatic. No further history on this patient could be obtained.

Comment. This case represents the scientific and rational treatment of pyelitis. A culture of the urine yielded *B. coli*. When constitutional treatment proved unavailing, the infected kidney was catheterized and irrigated and a catheter left in situ for three days, with apparent cure of this particular attack of pyelitis.

HAY FEVER*

Hay fever is a condition in which there is an irritation of the mucous membranes or the inner linings of the nose, throat and eyelids. The defensive mechanism against an irritation of the throat is coughing, against an irritation of the eyes is tearing or watering and against one of the nose is watering and sneezing. All these are attempts to expel the mechanical irritant. If the irritant, such as a pollen granule, is composed of irritants which are capable

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

A "Green Light to Health" broadcast given by Dr. L. Chandler Walker on Tuesday, April 16, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

of being dissolved by the watery secretion of the membranes, these soluble substances prolong the symptoms already mentioned, and in addition, cause itching and local swelling of the membranes. Anybody whose membranes are irritated by soluble irritants, and these are usually proteins, is designated as sensitive or allergic to those substances.

When one is subject to symptoms of hay fever more or less continuously or spasmodically throughout the calendar year, the term perennial hay fever is used. To determine the cause of this condition a detailed and searching history as regards the symptoms is very important. Occupation, exposure to dust, gases, odors, smoke and animals, the presence of pet animals or birds in the home, exposure to face powders, shaving powders, face lotions, very fragrant perfumes, flowers and soaps, exposure to frequently repeated sudden variations in the temperature, and the ingestion of beverages and drugs, all may be causes of perennial hay fever and may be suspected from the history of the individual. Foods also are a common cause of this type of hay fever, and tests may be done in order to determine whether they are implicated.

The simplest test, called the scratch test, consists of applying small amounts of specially prepared food substances to individual slight scratches on the forearm, to which is added a liquid to dissolve the food and permit of its absorption through the broken skin. If after an interval of fifteen to thirty minutes, a small raised blister, like a mosquito bite, appears at the site of any scratch, it is concluded that the particular food which was placed on that scratch is harmful to the individual and is probably the cause of hay fever. This test is also helpful for animal hair and skin scalings, for face powders, for feathers and for pollens.

The most prevalent kind of hay fever is seasonal in type, and the symptoms are limited to one or more of the warm seasons of the year. Pollens are chiefly responsible, although the various causes which I have mentioned for perennial hay fever may be secondary to or a complication of the pollen sensitization.

Pollens are divided into two classes, namely, those that are carried by insects and those that are borne by the wind. It is the wind borne group of pollens that cause hay fever. Another statement that is simple and nearly accurate is the following: the pollen of any tree, shrub or plant whose flower is highly scented or brightly colored rarely causes hay fever.

Here in New England we recognize three hay fever seasons: the early spring season, during late April and May, the early summer season, extending from late May to the middle of June, and the late summer or autumn season, which begins about the middle of August and extends to the first heavy frost. During the spring season tree pollens are the cause of hay fever. The birch and oak are the worst offenders, because they shed a large quantity of pollen over a period of ten days to three weeks. The willow and poplar also shed a large quantity of pollen, but only for a period of a few days. The various grasses are the cause of the early summer type of hay fever. It is from matured grass or hay, which was first recognized as a cause of symptoms, that the term hay fever is derived. June grass which pollinates in late May often causes a short attack of hay fever. Timothy grass is the chief cause of hay fever from early June to the middle of July. Other grasses either grow too sparingly or produce too small a quantity of pollen to be considered a prominent cause of hay fever. During the autumn season, in localities north of Connecticut, we are chiefly concerned with the pollen of small type ragweed.

Pigweed, plantain and other members of this botanical family may rarely be a cause of irritation.

Treatment of the perennial type of hay fever consists primarily in the avoidance of the causative irritant. A food may be avoided, a floss or kapok pillow may be substituted for a feather pillow, a pet animal may be dispensed with, a non-irritating face powder, shaving powder or soap may be substituted for an irritating one. Where dust cannot be avoided, a mask may be worn over the nose and mouth.

A sea voyage is the only sure way of avoiding all kinds of pollens. Ragweed, however, is unknown in Europe, South America and Bermuda.

Fortunately, pollen hay fever may be treated satisfactorily. The treatment consists of a series of inoculations containing the causative pollen. After this pollen has been ascertained by skin tests, further ones are made with a series of dilutions of the pollen, these dilutions range from a strong solution of the pollen to a very weak solution. By this dilution test, it is possible to determine to what strength of pollen solution a person is sensitive, it might be considered more or less a tolerance test. This test is very important in that it determines what strength of pollen is safe to use to begin treatment. Furthermore, from this test may also be estimated the total number of treatments that are desirable.

The most generally used method of treatment is to begin inoculations about fifteen weeks prior to the usual onset of symptoms, and to give one inoculation each week up to the beginning of the pollen season. Each succeeding treatment is progressively stronger than the preceding one so that the tolerance to the pollen protein is greatly increased. The results from this method of treatment are usually excellent for the ensuing season, and if a similar series of inoculations are given for several successive years, there is a probability of permanent cure.

Overindulgence in certain foods that are closely related botanically to a pollen that causes hay fever may aggravate hay-fever symptoms during that particular pollen season. For example, the ingestion of large amounts of the cereal grains, such as white flour, by a person who is sensitive to and has hay fever from grass pollens, may increase the hay-fever symptoms. Naturally, a reduction in the quantity of the cereals taken in the diet is indicated.

Air-conditioning and air filtration of the sleeping room give a great amount of relief to those who are especially troubled at night. In fact one would have no hay fever if he spent the entire pollen season in such a room. Nasal filters are very helpful during the daytime provided all breathing is through the nose.

Sprays, various applications in the nose, and inhalers are of limited service, since the causative agents are continuously present, and the local applications are used only at intervals.

* * *

Q Why does a person become sensitive to or allergic to something?

A One probable reason is overexposure or overindulgence—an overstepping of one's normal tolerance. After the condition of allergy has been established in a person, he or she may transmit a similar tendency to the offspring; in other words, inheritance may play a part.

Q How do you actually know what pollens are in the air at certain times?

A Glass plates covered with a sticky substance are exposed to the outdoor air. Upon these plates pollen grains fall, and they may then be identified by the microscope.

Q You mentioned the most generally employed method

od of treatment for hay fever namely to begin treatment fifteen weeks previous to the usual symptoms. What can be done for those who do not start treatment so early?

1 Inoculations may be started only a few weeks prior to the season and continued during the season. Treatment given only during the season of hay fever is the least satisfactory

Q I have a friend who with pollen treatment, is completely free from symptoms with the exception of a few minutes in the morning and a short time in the evening. Can you suggest any help for the morning and evening symptoms?

A The sudden change in the temperature to which the scantily clothed body is exposed, namely the change from a warm bed to the cool air on arising and from the heat of the day to the cool damp air after sunset, may be a cause. A sudden chilling of the exposed parts of the body causes a reaction in the nose especially and in the eyes sympathetically. Less exposure in the morning and more clothing in the evening are the answers.

Q I have heard of as many as one hundred and fifty tests being done on an allergic patient. Are as many as that necessary?

A No, and furthermore the great majority of that number are impractical. A careful history taken by the physician will exclude many useless tests and will often suggest probable causes. At the most, thirty to forty-five tests, all of which may be done at one visit, are sufficient. For seasonal hay fever, only a few tests are necessary.

Q Is it possible for all skin tests to be negative with a person who has hay fever throughout the year?

A Frequently repeated head colds, a chronic infection or inflammation of the nose or sinuses is often not distinguished from perennial hay fever by the laity although a proper diagnosis can be made by the physician. In such a case, skin tests are negative because the condition is not caused by ordinary proteins, but more probably by those of bacteria. When all other methods of treatment have failed a course of treatments with an appropriate vaccine is often of value.

Q You mentioned occupation as playing a part in the cause of hay fever. Will you cite a few cases?

A Bakers frequently become sensitive to the flour dust of the cereal grains also escaping gas from the ovens may irritate the nose. Housewives who do considerable baking may become sensitive to flour dust. Soap powders and house dust frequently irritate the nose. Those who work in factories where, of necessity there is much dust or lint in the air sometimes develop irritable membranes. The installation of air filtration blowers and exhaust fans have greatly eliminated the dust problem in factories.

Q Do roses really cause hay fever and what is a rose cold?

A From practical standpoint roses do not cause hay fever. It is possible for cut roses indoors to become so dried up that the pollen will get into the air and in unusual cases this results in an attack of hay fever that lasts for only a few hours. The fragrance of any highly scented flower may irritate the noses of some individuals but this is not true hay fever. Out of doors, other pollens to which a person is sensitive may be deposited by air currents on the rose flower. In such a case when a person smells the rose he is inhaling some other pollen that is the actual hay-fever cause, but the rose is naturally thought wrongly incriminated. Before it was established that grass pollen is the actual cause of hay fever at this

season roses were blamed and the condition was called rose cold.

Q You have said that brightly colored and very fragrant flowers as a rule do not cause hay fever. The assumption then that goldenrod lilacs, Easter lilies and so forth cause hay fever is erroneous?

A The pollen of goldenrod is too heavy and too sticky to blow about, the same is true of Easter lilies. If however these are kept indoors for a long time and allowed to become dry the pollen will drop off and may be blown about. The fragrance of lilacs, violets, carnations and so forth may irritate the nasal membranes temporarily but they do not cause real hay fever. The fragrance of apple and peach blossoms may irritate some noses. Practically no flowers used for cutting cause real hay fever.

DEATH

NOBLE—ANNGETTE F. NOBLE M.D., of Westfield died April 30. She was in her eightieth year.

Born at Westfield, she attended the schools there and received her degree from the Woman's Medical College of Baltimore in 1893. She was a fellow of the Massachusetts Medical Society and the American Medical Association and a member of the Women's Medical Association.

A daughter, a sister, a niece and a nephew survive her.

WEINGER—MORRIS A. WEINGER, M.D., of Lynn died January 27. He was in his forty-second year.

Born in New York City he attended Columbia University and received his degree from Boston University School of Medicine in 1927. He interned at Christ Hospital, Jersey City, New Jersey and Dayton National Military Hospital. He was assistant in cystoscopy and clinical assistant at the New York Post-Graduate Medical School and Hospital, New York City and was assistant urologist at Midtown and Harlem hospitals, New York City. He was on the staff of the Lynn Hospital at the time of his death.

Dr. Weinger was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow and two children survive him.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

GILMAN—LOUIS L. GILMAN, M.D., of Rochester died at the Frisbie Memorial Hospital on April 12 after a short illness. He was born at Gilman Iron Works, September 1, 1863 the son of Andrew and Martha (Lodge) Gilman and was graduated from the Dartmouth Medical School in 1896. Dr. Gilman was an assistant surgeon in the United States Army from 1898 to 1901. He served in the Philippines as personal physician to General Fred Funston and also saw service at Puerto Rico. Long an enthusiastic horseman, Dr. Gilman had been recently re-elected president of the New Hampshire State Fair Association and had been appointed chairman of the Executive Board of the Medical Staff at the Frisbie Memorial Hospital which was organized about two months before his death when an offer of \$200,000 was accepted for a new hospital.

Dr. Gilman was a thirty-second-degree Mason and a past exalted ruler and life member of the Rochester Lodge of Elks.

He is survived by his widow, Elizabeth Gilman.

MISCELLANY

RED CROSS DRIVE

Orders for large quantities of surgical instruments, 10 field hospital units complete, 150 high-speed ambulances, each capable of carrying 4 stretcher cases, and 100 auxiliary hospital trucks have been placed by the American Red Cross, it is announced by Chairman Norman H. Davis. The supplies are to be given to Red Cross societies of belligerent European countries to assist them in caring for refugees and wounded.

Placement of these orders and others for essential supplies represented the first steps by the American Red Cross in expansion of war-relief activities. To finance this expansion the Red Cross, on May 10, announced a campaign to raise a war relief fund of a minimum of \$10,000,000. Prior to that date all relief activities had been financed from reserve funds of the organization and such contributions as were designated for that purpose.

In announcing the campaign to raise a minimum of \$10,000,000, Chairman Davis said: "Against great pressure we have delayed this appeal for funds hoping that we could, without it, finance the war relief expected of us. The great heart of America goes out to the victims of all wars. Our sympathies must not be empty expressions. We must send clothing, bedding, medications, surgical supplies. Relief must be sent as needed and not too late to be of use."

Up to the start of the campaign, the American Red Cross had spent approximately \$1,500,000 of its reserves and donations in helping sister societies in war affected nations care for the victims of hostilities. Chapters had spent an additional \$350,000 in the production of some 450,000 warm knitted and sewn garments and more than 2,000,000 surgical dressings. More than 250,000 women volunteers are at work producing relief supplies.

MAINE NEWS

RECENTLY REGISTERED PHYSICIANS

The following physicians were licensed to practice medicine in Maine on March 13, 1949:

THROUGH EXAMINATION

C. Davis Belcher, Portland
William Blaisdell, Bangor
John A. Caswell, Bangor
Clement L. Donahue, Portland
George F. Emerson, Farmington.
Donald C. Gates, Gray
Paul D. Giddings, Augusta
Maximilian Hirschler, Lewiston
John Merrick, Portland.
Rosario A. Page, Bridgeport, Connecticut.
Hans Schurman, Lewiston.
Reinhold G. E. Ulpts, White Plains, New York.
Preston J. Van Kolken, Holland, Michigan.

THROUGH RECIPROCITY

Paul V. Davis, Warrenton, Virginia.
Samson Fisher, Bristol.
John T. Guy, Portsmouth, New Hampshire.
Joseph G. Ham, Portland.
Hyman Hillstein, Mt. Desert.
Joseph P. Reath, St. David's, Pennsylvania.

NEW ASSOCIATION MEMBERS

The following physicians have been recently admitted to membership in the Maine Medical Association:

J. B. Marcotte, Lewiston
Bernard Gagnon, Patten
F. F. Larrabee, Washburn
Robert B. Somerville, Presque Isle.
Joseph E. Poerter, Portland
Alfred Oestrich, Mexico
Alfred W. Norris, Jonesport.
Leon Nemon, Portland.

ANNUAL MEETING OF THE MAINE MEDICAL ASSOCIATION

The program in brief for the eighty-eighth annual meeting of the Maine Medical Association to be held at the Rangeley Lakes House, Rangeley, on June 23, 24 and 25, is as follows:

SUNDAY, JUNE 23

4 30 p.m. First meeting of the House of Delegates.
8 30 p.m. Entertainment for the doctors and their wives.

MONDAY, JUNE 24

9 30 a.m. to 12 00 m. Group conferences
12 30 p.m. Luncheon (tables reserved for the alumni of various medical schools and members of the Tumor Clinics)
2 00 to 4 45 p.m. Clinicopathological conference and scientific session
5 00 p.m. Election of president elect.
5 30 p.m. Second meeting of the House of Delegates.
7 00 p.m. Dinner and dancing
9 00 p.m. Address by V. W. Peterson, special agent, Federal Bureau of Investigation, Boston.

TUESDAY, JUNE 25

9 30 a.m. to 12 00 m. Group conferences
12 30 p.m. Luncheon (tables reserved for past presidents and county secretaries)
2 00 to 5 00 p.m. Scientific session
7 00 p.m. Banquet (dress informal)
Introduction of visiting delegates and guests by President George L. Pratt, M.D.
Presentation of fifty year service medals.
Address Governor Lewis O. Barrows.
Address Morris Fishbein, M.D., editor of the *Journal of the American Medical Association*, "Quackery in Medicine."

NOTES

At the annual meeting of the American Surgical Association, recently held at Washington University, St. Louis, Dr. David Cheever, associate professor of surgery, Harvard Medical School, was elected president for the ensuing year.

Dr. J. H. Means, Jackson Professor of Clinical Medicine, Harvard Medical School, was elected vice president of the Association of American Physicians during the recent annual meeting at Atlantic City.

At the annual meeting of the Austen Riggs Foundation, Incorporated, held in Stockbridge, Massachusetts, on May 11, Dr. Horace K. Richardson was elected medical director, succeeding Dr. Austen F. Riggs, who died on March 5. Dr. Robert B. Hiden was elected senior assistant medical director, and Dr. Charles H. Kimberly, junior assistant medical director.

CORRESPONDENCE

APPROVED SCHOOLS FOR LABORATORY TECHNICIANS

To the Editor I have recently seen in the *Journal of the American Medical Association* (114 1269 1940) and in the *American Journal of Clinical Pathology* (10.261 1940) that an unauthorized individual in New Jersey is circulating the medical laboratory technicians of New England asking them to join an irresponsible body calling itself the American Medical Technologists.

As New England appears to be fertile ground for such unauthorized activities I suggest that those concerned in the matter refer to the article in the *Journal of the American Medical Association* which justly points out the dangers of the efforts of such an organization to destroy the educational and clinical standards that have been created by the American Medical Association and the American Society of Clinical Pathologists for the practice of this vocation.

SIDNEY C. DALRYMPLE M.D., Pathologist

Newton Hospital
Newton Lower Falls, Massachusetts.

TUBERCULIN TEST

To the Editor Will you kindly publish the following note in regard to change in instructions to accompany Old Tuberculin distributed by the Massachusetts Department of Public Health

In the revised instructions which will accompany the Old Tuberculin supplied by the Department of Public Health for tuberculin testing suggestion is made that the test should be read in seventy-two hours rather than in forty-eight hours, as previously recommended.

Many years experience with the tuberculin test has established two reasons for this practice first, to avoid reading a pseudoreaction due to redness alone second to make it possible to observe occasional delayed reactions.

The criterion for a positive test is an area of edema at least 5 mm. in the broadest diameter in addition to erythema or redness. Redness (from trauma or irritation) occurs early and disappears promptly usually in forty-eight hours. Edema on the other hand when present persists for many days. In a seventy-two-hour reading of the test the edema will still be present when the redness has entirely disappeared.

The seventy-two-hour reading is particularly desirable when the 1-mg dose is used to retest children who fail to react to the first injection of 0.1 mg. of Old Tuberculin.

PAUL J. JAKUBOWICZ M.D.,
Commissioner of Public Health

State House Boston.

MEDICAL OFFICER, NATIONAL GUARD

To the Editor There is a vacancy as first lieutenant in the Medical Department Detachment of the 110th Cavalry Massachusetts National Guard. Any graduate of a Grade A medical school below the age of thirty-five and in good physical condition may apply. Since this regiment leaves for its maneuvers in June, those who are interested should

make an early application. Further information may be obtained from my office.

DAVID B. STEARNS, M.D., Commanding Officer
Medical Department Detachment, 110th Cavalry

416 Marlboro Street,
Boston.

REPORTS OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on February 6 1940 with Dr. Max Ritvo presiding. The first paper was by Dr. Herbert I. Harris on "Group Psychotherapy." After a short résumé of the history of the movement from Déjerine in 1904 the speaker went on to the purposes and aims of group therapy at the Pratt Clinic. It has been found that psychoneurotics are inclined to be obstinate, especially in the hands of the general physician or of the specialist in a large clinic the one prerequisite of their successful treatment is the long time necessary for each patient, which these men are unable to afford. The group method of psychotherapy was conceived, therefore, as an effective filter that would adequately take care of the less severe cases and refer the refractive patients to a special psychiatrist.

The technique employed at the Pratt Clinic was described as childish in its appeal thus imitating the usual responses of such patients. Several classes are held each week and any new members are given front-row seats, where they command some attention. Older members are urged to make friends with these novices, and thus an increase in social intercourse is afforded both patients. Each person is assigned a definite number in order to inflate the ego, and all old members of the group hand in an anonymous record of their progress which is read aloud. These reports are placed in three piles according to their progress and the large preponderance showing great improvement was described as a great encouragement to doubtful new members.

Dr. Harris stated that one of the most important concepts employed is that these people are really suffering and that their pains are not just imaginary. The patients are urged to attain true muscular relaxation as an antidote for their existing tension.

The results of group psychotherapy at the Pratt Clinic during the past eighteen months were reported as promising. Of all the patients admitted to the medical clinics 26 per cent were referred to the psychiatric clinic. Of the new members of the group more than a third claimed improvement after the first treatment, while over a half showed eventual complete disappearance of symptoms. Sixty-eight per cent of all patients treated under the system were judged to have displayed marked to complete improvement. The best results are obtained in psychoneurotic patients, with some hope being held out for those who are psychotic and schizophrenic.

The next paper was presented by Dr. William M. Shedden on "Cancer of the Rectum." The speaker made a plea for early and accurate diagnosis of existing carcinoma and for adequate treatment of precancerous lesions when found. The need for extensive operation was considered to be the direct outgrowth of the late appearance at the clinic of 60 per cent of all such lesions. In the light of Duke's work, on the other hand, resection and colostomy were judged to be the safest procedure where palpation of the lymph nodes, even at operation may car

ry over a 60 per cent error Dr Shedden also favored Dukes's method of gradation based on the degree of penetration of the bowel and surrounding structures

Reasons cited for wrong diagnosis and delay of treatment included ignorance of anything more than "piles" among clinic patients, fear of lost time from work, and failure of the doctor to look for serious causes of symptoms in the presence of existing hemorrhoids, adenomas or fissures Dr Shedden suggested routine rectal examinations in all patients as a means of discovering asymptomatic lesions, and also the possibility of routine barium enemas if the cost could be sufficiently decreased It has been claimed by some surgeons that a properly performed digital examination will reveal any rectal lesion except those high in the sigmoid

The reasons for delay, which amounted to more than four months in 63 per cent of the patients studied, were varied Thirty-eight per cent had hemorrhoids, and 10 per cent had been treated for these prior to admission Almost two thirds of the people remained well nourished, and some were even obese Many had relief of constipation by mineral oil and a few had negative barium enemas The presence of a soft polyp was not inconsistent with malignancy and even metastases, while an improperly performed biopsy might well be returned as negative Dr Shedden concluded from these findings that the opportunities for increasing the number of cures of carcinoma of the rectum rest with the local physician rather than with the surgeon who finally performs the operation

Results at the Boston Dispensary revealed that these lesions were operable in 76 per cent of cases, and curable in 50 per cent, with a mortality of about 8 per cent

The next presentation was by Dr S J Thannhauser, who discussed 'Hyperlipemia' It was noted that although Spinoza recognized "milky blood," the phenomenon was not rediscovered until 1800 And although the finding is now usually considered in association with diabetes, Dr Thannhauser pointed out that newer partition methods indicate that some degree of hyperlipemia is far from a rarity The speaker stated, however, that the finding of various lipids in the circulating blood was merely a reflection of changes in the organs and not necessarily an indication of metabolism

The various causes of hyperlipemia were then briefly considered The alimentary type, which may result in a 100 per cent increase of the fat content six hours following a meal, was not considered abnormal or significant Dr Thannhauser stated that a true fat migration does occur clinically but that the route of the necessary nerve stimuli is not certain It seems to originate in starved tissue and the resulting hyperlipemia is consequently found in anemia, cachexia and so forth A third type is found in abnormal fat deposition, which may occur in hypothyroidism and idiopathic familial lipemia In the former case, all fats are increased, while the latter shows an elevation of only the neutral fats and an enlarged liver and spleen

A fourth form of hyperlipemia occurs in abnormal fat and carbohydrate metabolism, such as diabetes and von Gierke's disease Dr Thannhauser was of the opinion that the persistence of this condition after diabetes is controlled is due to chronic pancreatitis, which may then cause the leading symptoms The final cause of hyperlipemia cited by the speaker was a disturbance of the intracellular metabolism of the liver and spleen, such as is found in nephrosis, xanthomatosis and Gaucher's and Niemann-Pick's diseases An increase of the total lipids is found only in nephrosis and occasionally in Niemann-Pick's disease, whereas only lecithin and cholesterol are

elevated in xanthomatosis and there is a decrease of the total lipids in Gaucher's disease

The next speaker was Dr Samuel Proger whose subject was "Anorexia Nervosa or Hypopituitarism" Three such cases have been observed at the Boston Dispensary for periods varying from five to eight years They all showed certain of the characteristic signs and symptoms of anorexia, insomnia, loss of weight, amenorrhea, slow pulse, low blood pressure and low basal metabolic rate The return to normal was spontaneous in two cases, and coincident with the institution of insulin therapy in the third Hormonal and psychotherapy proved ineffective

Two patients returned after ostensible cure with unexplained edema of the lower extremities, while the third patient's course was complicated by generalized decalcification with spontaneous fractures

The problem brought up by Dr Proger was whether the condition was a neurosis or a functional hypopituitarism The effectiveness of psychotherapy in certain cases would be difficult to explain on the latter basis Furthermore, the whole syndrome is explainable on the basis of a voluntary anorexia following an emotional disturbance which soon becomes involuntary and leads to starvation, which can explain all the findings in this condition It was hypothesized that anorexia in such personalities may be analogous to excessive drink in certain other people as a release mechanism

The final paper of the evening by Dr Ethan Allan Brown was entitled "What We Can and Cannot Do in Allergy" The speaker chose to limit his remarks to common allergic conditions which he listed in the order of their showing skin tests as follows hay fever, asthma, eczema, urticaria and migraine Dr Brown stated that the lower incidence in the latter conditions merely means fewer cases are allergic, not that all such cases are less allergic Also, the presence of these latter diseases in known allergic patients usually indicates that there are multiple sensitivities

Hay fever was found to be 90 to 95 per cent allergic, and treatment produced the best results in that group Fifteen per cent received complete relief in the first year, and 30 per cent after two years, but the curve then leveled off rapidly Dr Brown, however, advocated perennial treatment of known allergic patients, for in that way more can be learned of secondary inciting factors and desensitization can thus be enhanced Only about 15 per cent of patients received no relief

In asthma patients true allergy was found to play a less important role while secondary factors, both physical and emotional, were indirectly proportional to the success of treatment Since therapy should be directed at the psyche as well as at the organic disease, Dr Brown stressed the importance of preventing rather than curing attacks, thus preventing anxiety The use of enteric-coated pills of epinephrine to ward off early morning episodes was described

In regard to eczema, the speaker reminded his audience that many of the symptoms were the result of secondary dermatitis and infection He suggested that intensive treatment of the local condition in those without proved allergy, which contains 40 per cent of this group, may result in permanent rather than temporary relief Such diligent therapy should be continued for four to six weeks after the skin is superficially well

Less than 20 per cent of patients suffering from urticaria were found to be allergic, and Dr Brown therefore urged the use of psychotherapy where emotional factors play a role The speaker emphasized that people are prone to blame the obvious rather than the possible true

cause of such eruptions. He has never found hives from strawberries and has never obtained a positive skin test in such alleged sensitivities. In the case of migraine, specific prophylaxis and desensitization are efficacious in the small percentage of cases exhibiting demonstrable allergy but the therapy of the others has been found unsatisfactory.

NEW ENGLAND PEDIATRIC SOCIETY

On February 7 the New England Pediatric Society held a symposium at Longwood Towers, Brookline on the treatment of meningitis. The first speaker was Dr. Josephine B. Neal of New York City who discussed "The Treatment of Epidemic and Streptococcal Meningitis." Dr. Neal mentioned that the results of all serum treatment have been confused in the past by the lack of an adequate means of standardization, particularly with the introduction of a new method. Further confusion of evaluation results from the variation in the type of the disease, which may be primarily septicemic or in the meninges, and also from the introduction of antitoxins which may have some antibacterial action.

In a large series of cases of meningitis the etiologic agents in the order of their incidence were meningococci, pneumococci and streptococci. The epidemic form was found most frequently during the first year of life.

In regard to therapy of meningococcal meningitis, Dr. Neal advised the combination of drug and serum treatment rather than the use of serum or drug alone. Serum should be given intraspinally where there is no septicemia, and should be continued until two successive cerebrospinal fluid cultures are negative. In case of clotting ventricular rather than cisternal puncture was considered the safer procedure. In patients with septicemia 25 to 50 cc. of serum intravenously twice a day was suggested but this route was advocated only as a supplement to intraspinal therapy.

Although most cases responded to drug therapy some strains have proved to be drug fast. Therefore, in drug treated cases, serum should be given if no response is noted within a short time. Sulfapyridine, although somewhat more irregular in its action has seemed more promising according to early studies than sulfanilamide. Dr. Neal reported a case fatality of 27.4 per cent for all her hospital cases, which often included very late ones.

In the treatment of streptococcal meningitis, chemotherapy has produced a drop in mortality to 28.3 per cent. Dr. Neal recommended the use of Neoprontol rather than sulfanilamide, for it can be used intramuscularly and is efficient in lower concentrations. Therapy should be continued for at least one week even when the course is favorable, and lumbar punctures should be carried out routinely for their therapeutic effect and in order to obtain cultures. The usual careful supportive regimen was suggested in addition to transfusions as indicated by regular blood studies.

Dr. LeRoy Fothergill spoke on "The Treatment of Influenza Meningitis." The increased incidence of this form of the disease, which has raised it to first place at the Children's Hospital, was emphasized by the speaker. It occurs most commonly between the ages of two months and two and a half years, when the circulating antibodies have been shown to be minimal. Prior to that time natural antibodies are present, whereas the infant's own immunity as a result of repeated slight exposure, does not reach adequate levels until the third year.

Haemophilus influenzae is a group consisting of many heterogeneous organisms, of which those causing meningitis are usually homogeneous. For the manufacture of ef-

fective antiserum it is necessary to employ virulent strains, and the isolation and crystallization of the specific polysaccharide gave hope of a more potent serum the speaker indicated.

The mechanism by which serum exerts its action in influenza meningitis differs from the usual form in that destruction results from lysis by antibody and specific complement rather than from phagocytosis. This has practical applications, for it was recommended that complement be of the human variety and that this ingredient always be injected intraspinally to compensate for the normal absence of complement in the cerebrospinal fluid.

Dr. Fothergill suggested the use of one or two intravenous injections of serum to counteract bacteremia, and the use of serum and specific complement intrathecally. He stated that drugs had been used in addition, but that so far no improvement had resulted. Reduction in mortality has progressed from almost 100 per cent before serum to 84 per cent with the original serum and to 75 per cent with the improved serum made from virulent bacteria. The speaker quoted 6 recoveries in 12 cases treated by Alexander, who has been using rabbit rather than horse serum.

An interesting "washing" experiment was cited by Dr. Fothergill as a possible explanation of the failure to lower the mortality more substantially. This indicated that *H. influenzae* may survive intracellularly and so resist destruction. The sugar content of the spinal fluid was suggested as a good prognostic sign.

The final paper of the evening was by Dr. Maxwell Finland who spoke on the "Treatment of Pneumococcal Meningitis." This agent is the commonest cause of meningitis in adults and is second in importance in children. Trauma was found an important predisposing factor at the Boston City Hospital, being surpassed in importance only by infections of the upper respiratory tract, paranasal sinuses and middle ears.

Dr. Finland pointed out that in this disease adequate phagocytes, besides specific antibodies and complement, are necessary for destruction of the bacteria. Sulfanilamide alone has been shown to inhibit growth of the pneumococcus, clear a low grade bacteremia and decrease, without eliminating, the meningeal infection. The addition of specific antiserum, however, sterilizes the blood stream and meninges. The speaker stated that when serum is used in conjunction with chemotherapy only a small amount of antibody and complement are necessary except where there is evidence of a local abscess or pneumococcal endocarditis.

Dr. Finland pointed out that the types of pneumococcus usually found are those of the nasopharyngeal flora, with Type 3 predominating. In this form of meningitis there are unusually large numbers of bacteria and tremendous amounts of specific soluble substance. On the other hand complement is only rarely present and will rapidly disappear if introduced. Furthermore, there are no "natural" cerebrospinal antibodies and those introduced intravenously do not reach this space.

Experiments cited by the speaker showed that despite an adequate concentration of sulfapyridine, pneumococci continue to increase for forty-eight hours. Then there is a subsequent killing off of bacteria even in the absence of demonstrable antibodies. This occurs only with susceptible strains, a fact which cannot be ascertained beforehand. It was concluded that the combination of chemotherapy and specific antiserum was the best method of treating pneumococcal meningitis.

The technic employed at the Boston City Hospital consists in the drainage and immediate culture of the cerebro-

spinal fluid Large doses of sulfapyridine are administered and intravenous serum injected Intrathecally, one should inject either the patient's own serum or specific pneumococcus antiserum and complement Sufficient fluids should be administered to ensure cerebrospinal fluid for drainage, and lumbar punctures should be performed frequently until normal The drug is continued for at least seven to ten days, and transfusions should be given whenever indicated.

Twenty-one per cent of all cases treated with chemotherapy at the Boston City Hospital in the past three and a half years have recovered Comparison of various combinations of therapy indicated that the use of drugs and serum is necessary in many cases of pneumococcal meningitis, and should therefore be used in all cases until more is known of the mechanism of action Combined therapy in a small group resulted in the survival of 47 per cent

In discussing the papers, Dr Kenneth D Blackfan suggested that more attention should be focused on the entire patient until additional advances are made in specific therapy He warned of the comparison of statistics gleaned from seasons when the virulence of the organism and the resistance of the host are variable The importance of early diagnosis was stressed, and its difficulty alluded to, particularly in children.

NOTICES

TRUDEAU SOCIETY OF BOSTON

A meeting of the Trudeau Society of Boston will be held at the Bristol County Tuberculosis Sanatorium, Attleboro, Massachusetts, on Tuesday, May 28, at 4 00 p.m.

PROGRAM

The Role of Atelectasis in Pulmonary Tuberculosis
Dr Felix Fleischner

Presentation of Cases

Cases illustrating problems in management. Dr
Garnett P Smith.

Follow-up cases of bilateral disease in an adolescent.
Dr P E Johnson.

Two cases illustrating extrapleural pneumothorax
Dr R. H. Betts

Cases illustrating lack of deformity following thoracoplasty Dr William R. Rumel

Discussion of case for differentiation diagnosis Dr
Richard H. Overholt.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

| CLINIC | DATE | ORTHOPEDIC CONSULTANT |
|-------------|---------|-----------------------|
| Salem | June 3 | Harold C Bean |

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The spring meeting of the New England Obstetrical and Gynecological Society will be held at the Mary Fletcher Hospital, Burlington, Vermont, on Wednesday, June 12. Registration and operative clinics will be held from 8 30 a.m. to 12 00 noon Luncheon will be served at the Burlington Country Club at 1 00 p.m., and a meeting of the executive committee will be held at 1 30 p.m.

A dry clinic at the Fleming Museum will take place at 2 00 p.m. There will be a symposium on pelvic trauma and relaxations The program will be as follows

Obstetrical Conservation of the Birth Canal Episiotomy, secondary repairs and so forth Dr H. A. Durfee

Restoration of the Birth Canal Anterior and posterior plastic operations and the Kennedy operation for urinary incontinence. Dr B F Clark.

Prevention and Treatment of Retroversion Dr E. D. McSweeney

Surgical Cure of Uterine Prolapse. Dr O N Eastman.

There will be a general meeting of the society and assembly at the Burlington Country Club at 5 00 p.m. Dinner will be served at 6 00 p.m.

JEFFERSON MEDICAL COLLEGE ALUMNI ASSOCIATION

During the meeting of the American Medical Association in New York City, the Jefferson Medical College Alumni Association will hold its reunion banquet on Wednesday evening, June 12, at 7 o'clock, at the Murray Hill Hotel, Park Avenue, at 41st Street. Tickets are \$2.50 each. Requests for reservations should be addressed to Dr Thomas F Duhigg at that hotel, but all alumni are urged to attend even though they have neglected to make reservations.

AMERICAN NEISSERIAN MEDICAL SOCIETY

The sixth annual session of the American Neisserian Medical Society will be held at the Shelton Hotel, New York City, on June 10 and 11 The program will consist of the presentation of papers on the biology of the gonococcus, vulvovaginitis and the prophylaxis, diagnosis, treatment and cure of gonococcal infection.

All who are interested are cordially invited to attend the meetings

PAN AMERICAN CONGRESS OF OPHTHALMOLOGY

Plans for a Pan American Congress of Ophthalmology to be held at the Hotel Cleveland, Cleveland, Ohio, October 11 and 12, have been announced

The congress will be sponsored by the American Academy of Ophthalmology and Otolaryngology, an organization of more than 2500 specialists in diseases of the eye, ear, nose and throat, which will hold its annual convention immediately preceding the Pan American gathering

The United States Department of State has expressed its interest, and the governments of all the countries of the Western Hemisphere have been invited to send official delegates It is believed that the meeting will do much toward bringing about an *entente cordiale* among scientific men of the two Americas, and it is expected that a permanent organization will be effected

Papers in Spanish or Portuguese will be made understandable to English speaking ophthalmologists by the use

of lantern slides projecting a synopsis of each paragraph translated into English. The reverse process will be used with the English papers. Spanish and Portuguese stenographers will be present to record the discussions in the language of the authors.

The congress is open to any ophthalmologist who wishes to register. Individual invitations have been sent to about 1800 members of the ophthalmologic profession in the Latin-American countries as well as to the national societies of eye specialists and the universities. Individual invitations have not been sent to ophthalmologists in the United States and Canada but official invitations to them are being printed in the various journals of ophthalmology. A fee of \$5 has been set for membership in the congress.

More detailed information may be obtained from Dr William P. Wherry 1500 Medical Arts Building Omaha Nebraska.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY MAY 26

TUESDAY MAY 28

- *9-10 a.m. Personality Factors in Internal Medicine. Dr C. Macle Campbell. Joseph H. Pratt Diagnostic Hospital.

WEDNESDAY MAY 29

- *9-10 a.m. Hospital case presentation. Dr S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

FRIDAY MAY 31

- *9-10 a.m. Changes in the Circulation Produced by Poor Postural Adaptation. Dr Eugene A. Stead, Jr. Joseph H. Pratt Diagnostic Hospital.

*Open to the medical profession.

BOOK REVIEWS

Blood Groups and Blood Transfusion Alexander S. Wiener. Second edition. 306 pp. Springfield, Illinois, and Baltimore Charles C Thomas 1939 \$5.00.

The second edition of this well known work has clarified a number of subjects which were formerly not clearly understood therefore a good deal of new material has been added to every chapter and some of the old material has been deleted. The application of blood grouping to medicolegal work has been treated in more detail and the section on the grouping of blood stains has been completely rewritten and expanded.

In the chapter on the technique of blood transfusions there are several points in regard to the citrate method which require correction. The author apparently approves the straining of citrated blood through gauze before injection into the patient. In the reviewer's experience, however this has often led to clotting of the blood because of the presence of calcium salts in the bleached gauze. This is an obvious chemical reaction since calcium precipitates soluble citrates.

In ascribing to Marriott and Kekwick a citrate apparatus which is completely enclosed, the author apparently is not aware that this method was used by the United States Army Medical Corps during the World War. Furthermore, in regard to continuous drip transfusions, it should be mentioned that Marriott and Kekwick did not describe this technique until seven years after it had been in common use in certain hospitals in the United States. Fortunately the author points to the dangers inherent in the use of preserved and "bank" blood—a warning particularly timely with the increased and sometimes uncritical enthusiasm for this technique.

As usual the publisher and printer have done an excellent job. It is a volume which should be on the shelf of every physician.

In Memoria del Prof. Fabio Rivalta. Società Medico-Chirurgica di Romagna. 398 pp. Faenza Italy Fratelli Lega 1939.

On September 18 1938 at Cesena Italy the Società Medico-Chirurgica di Romagna held a meeting of commemoration for Prof. Fabio Rivalta, who had died on September 2. In connection with this meeting, the society has published a memorial volume, to which thirty three of his students and friends have contributed articles covering all the fields of medicine. The volume also contains a good portrait, a short biography and a bibliography of his writings.

Prof Rivalta was best known for the discovery of the so-called "Rivalta reaction" for the differentiation of transudates and inflammatory exudates, which he first described in 1910. In the memorial volume this subject is discussed in three articles by Drs. Chiodini and Gironi.

Health for New York City's Millions. An account of activities of the Department of Health of the City of New York for 1938 with comparative vital statistics tables Edited by Savel Zimand. 295 pp. New York Department of Health, 1939.

Dr. Rees's informative and substantial record of the activities of the Department of Health of New York City for the year 1938 is an effective answer to the criticism that records of health department activities are of necessity as dry as dust. With no sacrifice of accuracy this volume presents all the information essential to a health-

department report in an exceptionally readable form. In part the success in presentation of the material is due to the use of brief statements of the underlying plan or policy at the beginnings of chapters which lead the interest up to the facts themselves. The judicious use of photographs adds materially to the attractiveness of the book for the lay reader.

To the health officer this is an impressive record of well balanced municipal health administration. An outstanding feature of the New York City program is the development of neighborhood health centers throughout the city. This is the most effective method yet tried for bringing health services to the people in urban communities and is indispensable in a city the size of New York. The epidemiologist may feel somewhat confused to find case rates and death rates for whooping cough based on the estimated population under five years of age, the rates for measles on the population under fifteen, and the rates for poliomyelitis on the total population. The emphasis on age susceptibility is important, but comparison becomes difficult.

To the physician such a report is a reminder of how far public health can supplement medical treatment without invading the field of practice. More than that, in such activities as the consultation chest services for physicians and the pneumococcus-typing stations, the health department is making available to the general practitioner services which he cannot readily provide for himself.

The Story of Surgery Harvey Graham 425 pp. New York: Doubleday, Doran & Co., Inc., 1939. \$3.75

The author of this book has assumed the pen name of Harvey Graham, and is said to be a distinguished British physician, his identity is unknown to the reviewer. His *Story of Surgery* is in many ways a remarkable and unique book. Avowedly a "story book," it is in fact a readable running narrative of the evolution of the science and art of surgery from prehistoric times to the present, told with humor and essential historical accuracy but with occasional excursions of the imagination, which fill in the factual lean spots, to the great satisfaction of anyone but a scholar. The author defines his purpose by saying that it is not a history book or historical treatise, and that it should be read by "an ordinary man or woman—as distinct from that nebulous and rather awe inspiring creature the intelligent layman." There are no bibliographic notes, but an appended list of sixty-odd books and monographs, comprising the chief source material, and indices of names and subjects. There are twenty-three admirably executed plates, among which New England readers will be glad to see the familiar painting of the first operation under ether, at the Massachusetts General Hospital.

The stories of the greatest figures in surgery—Paré, Harvey, Hunter, Lister—are admirably told. It is perhaps in the account of contemporaneous surgery and in prognostication of the future that the author is least happy. Few will agree that "Russia is untrammelled and ahead in all the sciences of medical research" or that "diabetic gangrene is now a surgical rarity," or that the female relatives of a woman with cancer of the breast are several times more likely to develop the disease than are other women and therefore that any lump should be treated by complete mastectomy. The part played by American surgeons in modern surgical progress is by no means adequately portrayed, an example of which is the attribution to "Dr. McBurney of Roxbury" of the chief part in the evolution of the surgical treatment of appendicitis in America. Halsted's contribution was rub-

ber gloves, and Cushing is not mentioned in connection with brain tumor.

The *Story of Surgery* may be confidently recommended as entertaining and instructive reading for doctors and for such laymen as have more than a casual interest in the subject.

Tumors of the Skin Benign and malignant Joseph J. Eller 607 pp. Philadelphia: Lea & Febiger, 1939. \$10.00

This book will be valuable to medical students, physicians and dermatologists because the subject—tumors of the skin—is comprehensively discussed in one small volume. The appearance of benign and malignant new growths is adequately described, as well as the etiology, prognosis and treatment, and a clear picture is presented in a readable manner. The chapters on carcinomas of the skin with the differentiation of the basal-cell and squamous-cell types might arouse controversy among some pathologists, but it corresponds with the opinions of many dermatologists. The diagrammatic examples of these lesions in special locations, with suggested methods of therapy in their prevention, contain many valuable and practical ideas. Radium plaques properly constructed as to size and strength have been found of more value in the treatment of various cutaneous lesions than are radium tubes, and, in the opinion of the reviewer, are more practical in the treatment of superficial tumors where superficial radiation is indicated. It is interesting and refreshing to read a book written by a dermatologist who has the courage to outline an intelligent and workable technic for cutaneous surgery, which, with proper instruction, could be and should be mastered by young men entering dermatology. The principles and technic of roentgen and radium theory are clearly expressed. There is an excellent appendix containing practically all the data on radiation, physics and biology, including dosage tables and charts.

The Vitamins A symposium arranged under the auspices of the Council on Pharmacy and Chemistry and the Council on Foods of the American Medical Association 637 pp. Chicago: American Medical Association, 1939. \$1.50

The achievements in the science of nutrition in recent years have been numerous as well as most significant in the realm of modern medicine. The original vitamin alphabet has been greatly extended, and some of them have been subdivided. Research in vitamins tends largely toward their isolation and synthesis. New factors have been discovered which concern the growth of animals, their prothrombin content, abortion in cattle, effects on the endocrines and a variety of physiological effects. In view of the galaxy of diverse work on vitamins, new discoveries and rapid progress, this symposium is more than welcome.

Each chapter is written by distinguished investigators in their respective fields. Clearly written and understandable, without confusing excursions in intricate details, it is recommended to all. It should be a relief to those who up to now have depended on the somewhat exaggerated interpretations expressed in the pamphlets issued by pharmaceutical houses. In the introduction Dr. Morris Fishbein warns "the public and the medical profession against the commercial exploitation of individual vitamin preparations and particularly against the promotion of mixtures of vitamins as panaceas." This volume clearly presents the clinical and laboratory aspects of vitamins and deserves unrestricted praise.

NUMBER 22

IMMUNITY TO VIRUS DISEASES*

Some Theoretical and Practical Considerations

ERNEST W. GOOPPASTURE, M.D.†

NASHVILLE, TENNESSEE

ONE of the great difficulties encountered in the study of immunity from an experimental standpoint is the fact that, so far as medicine is concerned, there are few infectious diseases of man that can be induced in experimental animals with sufficient exactitude and constancy amidst conditions simulating those under which they make their appearance naturally, to enable the investigator to translate his experimental data in terms of spontaneously occurring disease. This difficulty has tended to divert the attention of investigators away from studies of pathogenesis—that is, the mechanism of infection, without a knowledge of which specific immunity cannot be fully understood. Possibly it has been easier in the laboratory to follow and to measure the antibody response of an animal to the parenteral injection of various antigens than it has been to observe and to trace the progress and mechanism of spontaneous or induced infection. To understand the mechanisms of defense one should be able to watch the varying tide of battle between the active agent and the host, and to appreciate more intimately the tactics of the latter as it succeeds in gaining and maintaining the upper hand.

This perhaps can be more readily accomplished, at least to a certain extent, with viruses, because each of these agents affects a certain type or types of cells in a very specific way and often leaves cytologic traces of its progress.

Among the great basic facts of immunity are three that merit consideration: first, that there are relatively few types of microbial parasites that under ordinary conditions of life are capable of inducing infective disease, and each as a rule only in a limited number of varieties of hosts, the others

being naturally immune, secondly, that the host is usually capable of offering active opposition to the advance and destructive influences of an established infection, and, finally, that after recovery the host is often as a result of the experience of infection, much more resistant than before to a second infection by the same agent—that is, it acquires immunity. Except that every virus that is known is a pathogenic agent, the above facts are likewise the foundation of knowledge of immunity to viruses.

During the course of and following many infective diseases, changes take place in the circulating plasma of the host that are expressed by specific phenomena which make their appearance when the infectious agent or some of its products, or both, are brought into contact with the serum under appropriate conditions. These phenomena are agglutination, precipitation, lysis, complement fixation, toxin neutralization, opsonization and, in the case of serum from hosts that have overcome many kinds of virus infections, a specific inactivating effect on the corresponding virus when mixed with it under suitable in vitro conditions.

The potential importance to acquired immunity of antibodies that circulate in the body fluids is especially evident in the case of infections caused by micro-organisms that grow in and spread by way of the body fluids or produce injurious soluble antigenic products similarly distributed to the body tissues as a whole. The protective and curative effect, for example, of circulating antitoxin that combines with and neutralizes diphtheria toxin in vivo is apparent, and the beneficial influence on the course of pneumococcal pneumonia of type specific antipneumococcus serum is explainable by virtue of the demonstration of the destructive effect of such a serum on the protective capsular polysaccharide that confers the antigenic specificity on each type and determines the production of an

*The Shattuck Lecture, delivered at the annual meeting of the Massachusetts Medical Society, Boston, May 21, 1940.

Professor of Pathology, Vanderbilt University Medical School; pathologist-in-chief, Vanderbilt University Hospital, Nashville, Tennessee.

antibody peculiar to itself. Dissolution of the capsular material renders the pneumococcus a prey to phagocytosis by leukocytes in whose cytoplasm the denuded diplococci disintegrate.

But the toxin of the diphtheria bacillus and the capsule of the pneumococcus are surrounded by the body fluids because of the natural extracellular position of these antigens in the mechanism of their respective infections, and they are presumably immediately affected by their respective circulating antibody.

Matters become somewhat more complicated when we consider recovery from and active resistance to certain other infections, for example typhoid fever. In the blood serum of typhoid-immune animals and human beings there are bacteriolytic, bactericidal and agglutinating substances and, to a lesser extent, precipitating and opsonic bodies, but no true antitoxins.

Notwithstanding the rather detailed knowledge of antigenic constituents of the typhoid bacillus and of the numerous antibacterial effects elicitable from immune serum, it is admitted that from a theoretical standpoint the importance of specific antibodies in recovery and resistance is uncertain because the bacteria frequently disappear from the blood long before the patient is cured.

Furthermore, although one attack of typhoid fever protects against subsequent infection, circulating antibodies disappear from the blood of typhoid convalescents usually within the first seven months after recovery. The more durable immunity, therefore, cannot well be attributed to them, but rather to a greatly enhanced capability of response to small amounts of antigen on the part of the cells that have become accustomed, as a result of infection, to producing them rapidly and effectively.

Infection of man with the typhoid bacillus seems to entail a very complicated series of events, and until the background of pathogenesis of the disease is better understood one will probably not know just what protective mechanisms are involved and in what ways. The whole course of events in typhoid fever, a disease not yet reproduced in lower animals, is not explainable on the assumption of an extracellular parasite liberating antigens that are responded to by antibodies capable of acting directly on the exposed bacilli to destroy them immediately or to promote their destruction by cells. Dr J W Adams and I^{1, 2} have recently presented evidence that the typhoid bacillus in human infections may be at times in the course of the disease an intracellular parasite, nourished and supported in growth by the cytoplasm of plasma cells in intestinal and mesenteric lymphoid

tissue. It would seem that so long as this intracellular reproductive phase of the infecting bacilli can be maintained, circulating antibodies should have little effect on them, and cessation of symptoms might ensue only after an undetermined break in this chain had taken place.

Intracellular infections by bacteria, protozoa and rickettsia introduce especial problems of their own, and they are possibly more closely related, as regards pathogenesis and immunity, to virus diseases than they are to extracellular infection, because the cell-parasite factor must be reckoned with in both instances.

The activity of viruses is as yet recognizable only by the changes induced in infected hosts, and all pertinent evidence indicates that these agents of disease require the internal medium of living cells for multiplication, whether they be inanimate molecules or obligate parasites. The hypothesis of cytotropism of viruses that formulates this doctrine is of great help in attempts to clarify and to render comprehensible the processes of pathogenesis, and to correlate them tentatively with the mechanisms of immunity.

Something of the cell-virus relation can be especially well demonstrated in fowlpox, a disease of birds that simulates variola in many ways, and its lesions may be correlated with the general pox group which includes not only smallpox, but alastrim, vaccinia and molluscum contagiosum. Fowlpox is an especially good example to illustrate the point at issue, because it is as yet the only virus disease in which the active agent has been proved experimentally to be inside infected cells and to be a constituent of a specific cellular inclusion such as one frequently finds in virus lesions. This experimental demonstration was made several years ago in collaboration with Dr C E Woodruff.³

The wart-like lesions of fowlpox occur particularly in the skin, usually as a result of secondary localization of virus carried by the blood stream from a primary focus, probably most commonly situated in the mouth. The lesion is characterized mainly by hyperplasia and swelling of epithelial cells, each of which contains a relatively large intracytoplasmic mass known as the Bollinger body.

Dr Woodruff and I found that trypsin in weakly alkaline solution rapidly freed the specific cellular inclusions of fowlpox from infected epithelial cells by dissolving the epithelial membrane and cytoplasm, so that the refractive inclusions, which are relatively quite large and substantial, could be obtained in quantity. By picking out individual inclusions with a micropipette and washing them in 2 per cent sodium chloride solution, until the washings no longer contained de-

monstrable active virus, we showed that a single washed inclusion inoculated into a feather follicle of a hen caused fowlpox infection at that site. Each well formed inclusion contains many thousand minute particles, uniform in size, coccoid in shape, measuring 0.25 micron in diameter and possessing definite staining reactions. These are incorporated in the inclusions by a lipoproteid matrix, and they are known as the specific elementary bodies of this disease. By means of an attenuated glass point and microdissector, we were able to break up a single inclusion and to inoculate several feather follicles of a hen with minute fragments containing elementary bodies, the result was multiple infections with material from one inclusion.

This evidence indicates very strongly that the elementary bodies of the fowlpox intracellular inclusion are associated with the specific virus of this disease, and that they become agglomerated, together with a lipoproteid matrix, within the cell into a cytoplasmic mass, the Bollinger body. It has also been demonstrated that the elementary bodies of vaccinia and of molluscum contagiosum are intracellular and are the most important constituents of the respective cellular inclusions.^{4, 6}

Further evidence that the elementary body of this and certain other virus diseases represents the virus particle itself is furnished by the facts that washed elementary bodies are infectious and that they are specifically agglutinable by immune serum.⁴

The peculiarity of virus infections as contrasted with most bacterial infections is this apparently necessary cell virus relation that not only determines the characteristic picture of a particular disease but underlies the portal of entry and spread of virus, as well as its multiplication in the invaded host. It is that relation also which by determining the pattern of pathogenesis in any particular virus disease lends an especial fascination to its study. The intracellular position of the infectious agent furthermore, may protect it from circulating antibody, and in other ways influence the mechanism of immunity.

A thorough understanding of the pathogenesis of particular virus diseases would involve a knowledge of such elements as portals of entry, primary infection dissemination, secondary localization and elimination, and, if the hypothesis of cytotropism is to be of help, all these phenomena in the infectious process must be exactly related to the particular type or types of cell primarily invaded and those secondarily infected in each case, for complete immunity might be due in some cases to an acquired specific resistance limited to the type of cell

at the portal of entry alone, other cells, such as those of the central nervous system, remaining susceptible. The cell virus relation probably varies with every virus, and these variations may be spectacular, conferring complicated patterns of disease on the infected host. A few illustrations will, I hope, suffice to illustrate the principle involved.

There are certain viruses of human disease that seem to multiply within and to affect only the epithelial cells of the skin, for example those of warts and of molluscum contagiosum. The infectious agent is brought into direct contact with exposed susceptible epithelium from without, although in the case of warts, injury may result in secondary foci by lymphatic spread. Metastases do not seem to occur as a result of blood-borne virus. In the first example of infection it is quite likely that cutaneous injury exposes epithelium to contact with virus from the outside. These viruses are referred to as epitheliotropic, and are presumably obligately so. Because the lesions are confined to the skin and shed their component infected cells to the exterior, it is possible that relatively little antigenic material gains entrance into the body, and these diseases tend to run a rather long course.

There are other virus diseases of man that are characterized clinically by a cutaneous eruption, and in the skin lesions, epithelial cells are likewise prominently involved. Examples of such diseases are smallpox, chickenpox and possibly measles. In the lesions of these diseases, certainly in those of variola and varicella, virus affects not only epithelial cells but also those of mesodermal origin, such as fibroblasts and endothelium. This is of importance with reference to spread and secondary localization of these infections, which evidently take place by way of the blood stream. A primary lesion occurs no doubt somewhere in the upper respiratory tract, thence virus liberated from infected cells gains entrance into the blood stream to relocate in the skin and internal organs, where there are accessible susceptible cells, to form secondary foci.

In a third group of virus diseases of man the nervous system is especially involved. Of this group the viruses of poliomyelitis and rabies seemingly are obligately neurotropic; that is, they appear to require the medium of neurones for their multiplication and spread.

The conception of cytotropism is of fundamental significance to an interpretation of the pathogenesis of such various types of infection, for, if it be true, then the portal of entry of each obligate neurotropic virus must be through neural channels. In the monkey, at least, this appears to be

the case with the virus of poliomyelitis, because following intranasal instillation the pathway of infection seems to be along the exposed filaments of the olfactory mucosa, thence by way of axones and dendrites to the olfactory bulb, thence to the brain and spinal cord. Similarly the bite of a rabid dog introduces rabies virus from the saliva into injured tissue containing exposed nerve processes, and it appears that it is through these endings and axones that the virus reaches the central nervous system, to disseminate there likewise through neural channels. Experimental evidence for neuronal spread has been obtained especially from studies of herpetic infection in rabbits.⁷

Other viruses that affect the nervous system are not so restricted in their requirements, but affect more than one type of cell. Among these are the viruses of St. Louis encephalitis, equine encephalomyelitis and yellow fever, in lower animals a good example of this group is the virus of canine distemper. Such viruses as these probably enter the brain to infect neurones or supporting tissue only by way of the blood stream, and the portal of entry might be a cutaneous injury, such as the bite of a mosquito, that exposes capillary endothelium and blood to the virus.

The viruses that affect more than one type of cell, such as those last named, have been referred to as polycytotropic viruses, and I regard this term as more appropriate than pantropic or viscerotropic, although the latter are often employed. The use of the term polycytotropic, however, does not obviate the necessity of demonstrating each kind of susceptible cell in every case, because from the standpoint of understanding these infections, their pathogenesis and eventually the mechanism of immunity to them, it is of great importance to know just what specific types of cell are affected and how cytotropism determines pathogenesis. DeMonbreun's⁸ studies of canine distemper show that not only epithelial cells but also vascular endothelium is susceptible to this virus. Infection of vascular endothelium is no doubt concerned with spread of the virus, and localization of the infection in the brain is probably not through neurones but by way of the vascular endothelium as the portal of entry from the blood stream. It is possible also that a similar mechanism exists in St. Louis encephalitis and equine encephalomyelitis. In yellow fever it might also be that endothelium is first infected, and that virus thence liberated into the blood stream localizes secondarily in the cells of the liver.

No virus has yet been cultivated in the absence of living susceptible cells, and because of this fact it is a difficult matter to obtain viruses in a state of purity and in quantity necessary for extensive

analyses. Their nature remains undetermined, but they appear to lie somewhere along the borderland of the living and the inanimate, possibly constituting a liaison between them. They are particles of different size, they contain nucleoprotein, and they are antigenic. Frequently recovery from infection is followed by specific resistance to reinfection that lasts for varying periods, from weeks to many years, and occasionally perhaps throughout life, depending largely on the type of virus. The striking immunity so often observed makes the virus infections especially interesting from the standpoint of acquired resistance, and has led to the practices of prophylactic immunization by passive transfer of specific serum or vaccination with modified active virus and even with non-infective preparations, which in some cases have proved to be effective.

As in bacterial infections, specific antibodies also appear in the serum of animals that have recovered from virus diseases or have been actively immunized by vaccination. The virus antibodies simulate in general those demonstrable as a result of infection or vaccination with bacteria, but it is to be especially emphasized that virus infection elicits the production of specific antibodies that, under proper conditions *in vitro*, have a neutralizing effect on the virus concerned, and that this reaction simulates the toxin-antitoxin reaction. In regard to immunity it is possible that the effect of this antiviral antibody at least in some cases is in relation to the cell-virus complex, as it might operate to prevent virus from entering susceptible cells.

But one must be cautious in such interpretations, and I wish to emphasize that the phenomena of active resistance to recurrence of a specific virus infection are not necessarily coexistent with the presence of these demonstrable changes in the serum. The occurrence of specific antibodies in the blood serum of recovered hosts does not always signify immunity, nor is there as yet a well-established relation of specific antibodies to the state of heightened resistance or immunity that follows natural virus infection. It has been shown, for example, in the case of vaccinia virus that a rabbit vaccinated with inactive elementary bodies to the extent that its blood serum contains abundant agglutinating, precipitating and complement-fixing antibodies is just as susceptible to infection with active vaccinia virus as is a normal rabbit.⁹ It would seem more likely that the antibody that neutralizes a virus *in vitro* is related in some way more directly to the mechanism of immunity than are those responsible for agglutination and precipitation, yet such experiments as those of Hodes and Webster¹⁰ with the virus of the St. Louis type of encephalitis

make it appear very doubtful that, in this infection at least, there is any such relation. These investigators showed that mice vaccinated with the St. Louis encephalitis virus become highly immune and continue so for six weeks after vaccination, at which time few or no neutralizing antibodies are demonstrable in their serums. Then immunity begins to wane, and as it lessens, neutralizing antibodies make their appearance and rapidly increase in amount, to reach their height twenty-two to twenty-four weeks after vaccination, at a time when the animals have ceased to be resistant to reinfection.

No toxins have been demonstrated in virus lesions, and consequently no evidence of antitoxins in immune serums has been found. Little is known about phagocytosis of viruses as a combative mechanism, or about the participation of complement in any destructive capacity.

It is obvious, therefore, that the mechanisms involved in immunity to virus infections are not at present clearly understood, and they are unlikely to be until a better comprehension of their relation to pathogenesis of these infections has been attained.

Notwithstanding the inability to explain the mechanism of immunity on the basis of known specific humoral antibodies, the rather anomalous situation exists that, in the case of at least a few viruses, infection can be prevented by a properly timed and measured dose of specific antiserum. This is an established prophylactic practice for the prevention of measles—presumably a virus disease. A similar practice seems to be of preventive effect against mumps, and experimentally it is effective to some extent against others, including vaccinia. These are empirical facts, however, and they do not elucidate the mechanism of heightened resistance. The explanation will no doubt eventually be found in additional knowledge concerning pathogenesis, which is determined by the cell virus relation.

Some students of virus diseases think that the formerly susceptible cells of a recovered host acquire a specific resistance as a result of virus infection, and that such a change is of equal or even greater importance in some cases than is the acquisition of humoral antibodies. But the assumption of acquired cellular immunity separate and apart from humoral antibodies has not been well substantiated by direct experiment.

I should like in this connection to refer briefly to some studies we¹¹ have made with the virus of fowlpox previously mentioned. These experiments were undertaken to determine whether or not we could find evidence of an increased cellular

resistance to infection in fowls with acquired immunity. This disease offered, we thought, an exceptionally favorable opportunity for experimental study of certain phases of this problem because the virus affects especially cutaneous epithelium, manifesting itself by easily recognizable specific cellular inclusions, and because the skin can readily be grafted onto the chorioallantois of chick embryos from both normal and immune fowls. The latter fact affords a favorable method for studying the behavior of cutaneous epithelium under different environmental circumstances.

Our first objective was to determine whether or not established skin grafts from normal and immune fowls were susceptible to infection with the virus of fowlpox, as manifested by the development of the pathognomonic Bollinger bodies within the cytoplasm of the epithelial cells following inoculation.

These experiments conclusively proved that the epithelial cells of skin from chickens with an acquired immunity to fowlpox and completely resistant to infection by cutaneous inoculation, while a part of the immunized host, become quite as susceptible to infection by this virus as do grafts of normal skin after grafting onto the chorioallantoic membrane. If such grafts, as well as those from normal chickens, were regrafted onto muscle of immune chickens and inoculated, no infection took place. Normal skin, on the other hand, if regrafted onto the muscle of normal chickens, was quite susceptible to infection by inoculation. We found no indication, therefore, of the existence of an acquired immunity inherent in the epithelial cells themselves, but our results pointed rather to humoral or local factors in other tissues as the cause of acquired resistance of the normally susceptible epithelium.

Under some circumstances acquired insusceptibility of certain cells of a host seems out of proportion to the concentration of demonstrable circulating antibody, and this is the case with epithelium of chickens immunized to fowlpox. One is tempted to conjecture that humoral antibody might be concentrated in the skin, perhaps inside the epithelial cells themselves, from the surrounding medium. When grafted onto the chorioallantois such antibodies would become diluted by the plasmatic circulation in the graft and thereby be rendered ineffective. There is little experimental basis for such an assumption, although the reported success of McKinley¹² and of Hallauer¹³ in conferring passive immunity to rabbits against intracerebral injection of herpes virus by repeated doses of immune serum, while no cerebral immunity could be demonstrated after a single large

dose, might be interpreted to mean that after a period of time circulating antibody kept at a high level by repeated administration might finally penetrate the cerebrospinal fluid or the nerve cells themselves, temporarily heightening their resistance

So far as our own investigations have enlightened us, immunity to those virus infections with which we have worked, especially fowlpox and herpes simplex, appears to be importantly contributed to by something of a specific nature circulating in the blood. What this something is and how it works to prevent or ameliorate infection we do not know. We should suppose it to be a specific antibody, but whether it is one of those demonstrable by *in vitro* tests or another as yet unrecognized is obscure. This hypothetical antibody to fowlpox does not necessarily operate in such a way as to prevent virus from entering susceptible cells and inducing typical lesions, as was shown by the following recent experiment

After a certain dose of hyperimmune hen's serum was injected intravenously into baby chicks, the down of whose heads had been plucked, and this was followed by an intravenous dose of fowlpox elementary-body suspension, just as many lesions developed in the injured skin, eyelids, mouth and stomach as appeared in controls treated the same way except that they received normal hen's serum. However, the controls rapidly became sick and died several days earlier than did those passively immunized. Some of the latter recovered after the lesions, which continued to increase in size for a while, aborted and healed prematurely. These experiments are not yet complete, but it seems at present that the immune serum might act, among other ways, to protect the chick against some injurious agent elaborated as a result of infection rather than to prevent the infection itself, although it certainly exerts an inhibiting effect on the full development of established lesions.

One is hardly in a position at present to exclude some active participation at times of the susceptible cells themselves in the immunity process, because actual infection of a given type of cell, for example the cerebral neurones of a rabbit with herpetic encephalitis, confers after recovery a strong immunity to subsequent intracerebral injection of herpetic virus that seems to be independent of circulating antibody, while keratitis alone, although it confers immunity to subsequent corneal inoculation and stimulates the formation of antibody, often does not protect the brain from infection by intracerebral inoculation.

It is possible that it is necessary for active virus to enter susceptible cells in order that they may

respond in some way to heighten their resistance, for example by the local formation of antibody. If this should be true it might explain the frequent failure to induce effective resistance by the injection of inactive vaccines. Active virus evidently has the capacity to enter susceptible cells, but if the virus becomes altered in such a way that it does not induce infection, that alteration might also be of such a nature as to destroy its capacity to gain entrance into cells ordinarily susceptible, and thus to elicit a protective response to it. But on this hypothesis one must assume that virus enters all susceptible cells, and there is no evidence of this at present. On the other hand, circulating antibodies might enter and to a certain extent become concentrated in the course of time in cells that do not produce them. Passive immunization of the brain of rabbits against an intracerebral injection of herpes virus by repeated injections of immune serum might be explained in this way, for a single large dose of immune serum is not protective.

There is one group of virus diseases that should be especially susceptible of modification or prevention by parenteral injection of immune serum, that is the group in which the virus is spread in early stages of the disease by the blood stream, particularly if endothelium is infected. In this group one might tentatively include yellow fever, variola, varicella and measles. One can reasonably assume an initial lesion from which virus is thrown into the blood stream, or an initial infection of vascular endothelium itself such as can be induced experimentally in canine distemper and in experimental herpetic infection of the chick embryo, which will be described later. If circulating antibody be present during the development of the primary lesion, blood dissemination and metastasis may be prevented or modified provided virus is exposed to antibody in the circulating fluid. In all likelihood this is the way in which an early administered dose of measles immune serum exerts its protective effect.

In another group of virus diseases, including especially those in which the virus seems to be obligately related to nerve cells, such as poliomyelitis and rabies, there would seem to be much less likelihood of favorably influencing the course of the infection by the introduction of immune serum, because virus can gain access to and spread through the nervous system by means of neural processes apparently without becoming subject to the influence of circulating inhibiting factors. Indeed, the use of immune serum in these diseases has been of no evident avail. Repeated injections of immune serum for several weeks before infection has taken place might, however, confer protective passive

immunity for a short while, in view of Hallauer's¹³ experiments with herpes simplex.

In the first group of diseases in which virus is blood-borne, the chances of effective immunization by a proper inactive vaccine would seem to be far superior to those obtaining in the second group in which antibodies actively or passively acquired circulate but do not presumably come into contact with intracellular virus.

The interrelation of pathogenesis of a virus infection and immunity cannot, I think, be illustrated better than by reference to clinical pictures and experimental infections caused by the virus of the cold sore or fever blister. Herpes simplex infection in human beings has several rather distinct and characteristic clinical manifestations, and it is quite likely that each is due to the particular balance existing at the time between susceptibility and immunity of the host and to the peculiar intimacy that obtains between the virus and certain types of cell.

The common type of herpes in adults is the ordinary labial variety, but rather recently Drs. K. Dodd, L. M. Johnston and G. J. Buddingh,¹⁴ at Vanderbilt University Medical School have identified herpes simplex virus as the specific etiologic agent of a stomatitis of infants and children that heretofore has probably been included in an indefinite group of diseases to which pediatricians have given the name "aphthous stomatitis." These investigators consider herpetic stomatitis, which is sometimes accompanied by rather severe general symptoms, as representing a primary infection. This point of view is maintained also by Burnet and Lush¹⁵ who confirmed the previous work, and found further that children who had herpetic stomatitis possessed no virus-neutralizing antibody in their bloods. Following recovery however, anti-body was present.

It would appear that subsequent attacks of herpes, occurring most commonly in adult life, take place in individuals whose blood serums already contain antibody signifying previous infection and that these people show no herpetic virus in their saliva during or between attacks. The presence, therefore, of antiviral antibody in the blood is not preventive of herpetic infection of the lip but probably owing to previous infection, indicated by the presence of antibody, the clinical manifestation is different in that the intraoral mucosa escapes.

In a third type of herpetic infection the eruption breaks out repeatedly in the same area of skin, and sometimes in definite relation to a particular cutaneous nerve. In these cases, neutralizing antibody is also present in the blood.

It is an interesting adventure in speculation to try to interpret such varied phenomena in terms of known fact and acceptable current hypothesis. It seems evident in the first place that circulating neutralizing antibody in such concentration at least as exists under the circumstances, is ordinarily not sufficient to protect epithelial cells of the lip from infection with herpes virus from the outside. In those cases where the cutaneous eruption is definitely related to a particular nerve there is more difficulty in explaining the phenomenon of infection, and at the present time it seems most logical to conclude that the virus remains latent within nerve cells over long periods, manifesting itself by infecting epithelial cells when unknown conditions arise to permit restoration of its activity. This is possibly true also in the case of the usual labial herpes, for in many cases there is no evidence of contact with extraneous virus. If the assumption of latent herpetic infection of nerve cells be accepted then one must reckon with a complex and variable intracellular immunity mechanism, concerning the nature of which there is no knowledge.

It may be concluded from the observed facts that, ordinarily at least, cutaneous epithelium in itself does not possess innate immunity in those subject to herpes, but that a change resulting from an initial infection, indicated by a virus-neutralizing effect of serum alters the clinical picture and course of subsequent infections.

Herpetic virus is very infectious for the rabbit, and much knowledge of the host virus relation has been derived from experimental infections in this animal. Inoculated on the cornea the virus infects the epithelial cells, inducing an acute keratitis. With many strains of virus the infection does not stop at the eye but proceeds rapidly to the brain, following the course of fibers of the sensory division of the fifth cranial nerve and utilizing the medium of the axis cylinders as pathways for its invasive progress. Frequently the encephalitis is fatal. The blood stream is not at all or rarely invaded. Should an animal recover from its encephalitis it is immune to reinfection, even by intracerebral injection of many lethal doses for normal rabbits, and because little or no circulating antibody may be demonstrable there is some reason for the belief that a specific resistance has taken place in the neurones themselves.

Miss Katherine Anderson,¹⁶ at Vanderbilt, has recently observed, in her studies of herpetic infection of chick embryos, the sudden appearance of a variant of the virulent HF neurotropic strain of herpes virus (Rockefeller Institute), which has become so altered by chick embryo passage that it

causes only a mild acute keratitis in inoculated rabbits, the infection stops at the cornea, and there is no invasion of the brain. These rabbits become immune to reinoculation of the cornea with the virulent HF strain, and neither keratitis nor encephalitis may follow a heavy inoculation, but the brain may remain susceptible to infection if virus is injected intracerebrally. Here, then, is a case in which as a result of the experience of a previous peripheral infection the host has become resistant at the portal of entry, while remaining susceptible to virus that might break through to reach the nervous system. Protection of a natural portal of entry, however, would be adequate no doubt in the ordinary course of events to prevent disease, and the modified herpes strain represents a desirable type of variant for prophylactic inoculation.

In human infection with herpes virus and in that induced in rabbits there is no evidence of blood-borne metastasis. Recovery from infection, however, may be associated with the appearance of antiviral antibodies in the blood stream. The presence of such antibodies is not incompatible with susceptibility to reinfection, although the resulting disease might be different from the primary infection, at least in man.

In connection with the pathogenesis of this infection and with reference to immunity, the recent success of Miss Anderson¹⁷ in inducing blood-borne metastases in chick embryos is of great interest. She has been able to adapt a strain of herpes virus, by repeated membranous cultures, to the tissues of chick embryos. By passage in this host the virus has become modified in such a way that its virulence for the embryo has become greatly enhanced, and its capacity to infect cells of mesodermal origin, especially endothelium, has become augmented. As a result of this change, inoculation of the chorioallantoic membrane results not only in a local infection of that structure, but also in an extension by continuity and hematogenous metastasis to a number of internal organs, especially the liver, heart, spleen and kidneys. The mechanism of hematogenous dissemination seems to depend on the enhanced ability of the virus to infect the endothelial cells of blood-vessel channels, thus initiating foci of infection that spread to cells of the parenchyma. Hematogenous spread by endothelial infection has not, I believe, been previously observed in herpetic infection of other animals, and Miss Anderson's experiments introduce a new element into the problem of pathogenesis of this interesting experimental disease.

Because extension of the infection from the membrane to internal organs appeared to be by way of vascular endothelium, an opportunity was

presented to observe the effect of passive immunization by means of intravenous injection of hyperimmune hen serum on the course of the experimental disease, and Miss Anderson was able to show quite clearly that intravenous introduction of such an immune serum not only inhibited or prevented blood-borne metastasis, but likewise modified the local lesion and prolonged the life of the embryo.

Thus it has been shown experimentally that the presence of circulating immune bodies may not prevent a local herpetic infection of the skin or brain, but that passively conferred humoral antibodies may prevent spread of the infection by way of the blood stream if that spread is associated with infection of vascular endothelium.

If one accepts the possibility of latent herpetic infection of human neurones or other cells, it must be assumed that resistance to virus activity during inter-eruptive periods is dependent on a rather delicate and variable intracellular chemical or physical balance of a temporary nature and probably not dependent on antibody, because a great variety of conditions, such as hyperthermia and proteid and chemical intoxications, are readily followed by evidences of reactivated pathogenicity, as manifested by an eruption of labial herpes. The idea of lability of cells in respect to their susceptibility and resistance to viruses seems to be a rather hopeful conception, because it points to the possibility of modifying cells intentionally in the direction of increased resistance by chemical or other means.

Different methods are being used at the present time with varying degrees of effectiveness to control or modify virus diseases. These methods have already been mentioned, namely active immunization by infection with a mild virus, active immunization by injection of inactive virus material and passive immunization by the injection of immune serum.

Active immunization by infection with a mild virus started with Jenner, and has been successfully employed ever since in the prevention of smallpox. In the last few years the same principle has been employed in the prevention of yellow fever and of certain virus diseases of animals. The outlook for this method is very hopeful, for strains of viruses are readily variable, and it has been possible to modify some of them experimentally so that they may be more safely used as active vaccines.

Active immunization for protection against yellow fever was made possible by the work of Theiler,¹⁸ at the Harvard Medical School, which showed that this virus can be modified in its virulence and pathogenicity by passage through the

brains of mice. Thus changed, the virus no longer induced yellow fever when injected subcutaneously into susceptible monkeys. This modified, so-called "neurotropic" yellow fever virus has been used for human vaccination, but another strain has been employed on a larger scale and probably with less hazard after modification by repeated tissue culture.

Immunization with an active virus is most effective if actual infection is induced, but the induced disease must be mild and without important hazard if it is to be successfully applied in human prophylaxis. In some cases the use of an active virus so attenuated that it does not induce infection might be superior to an inactive product, because of better antigenic properties. This can be accomplished with some viruses by introducing them into tissues whose cells are not naturally susceptible. Pasteur, for example, finished his vaccinations for rabies with active virus in emulsions of rabbit cord injected subcutaneously, preceded by several injections of inactive material. It would, of course, be an unsafe procedure in any case to attempt human immunization with an infecting dose of virulent virus.

Injection of specific immune serum at a proper time will prevent or modify measles, and immunization with inactive vaccines has been used to protect against rabies, with, at least in the dog, uncertain success. Inactive preparations of the virus of equine encephalomyelitis cultivated in the chick embryo appear to be quite satisfactory in protecting horses and perhaps man. Antiviral antibodies appear in the serum of vaccinated animals following injections of the inactive vaccines in each of these cases, but in view of the circulation of virus in blood and the susceptibility of cells presumably of mesodermal origin in the case of equine encephalomyelitis, it is perhaps simpler to attribute protection against that disease to the presence of such antibodies—an assumption which is more questionable in the case of induced immunity to rabies, where the virus in the usual course of events does not necessarily contact circulating antibody.

Protection by vaccination with apparently inactive material against such a virus as rabies has raised the question in many minds as to whether the vaccines that do protect are entirely free of active virus, although the infection be inapparent. Unfortunately there is no way to be absolutely sure about this at present.

There is still hope, however, of inducing variations in obligate neurotropic viruses,—such as those of rabies and poliomyelitis,—similar to those already found in the case of the virus of small

pox and of yellow fever, that will induce without hazard a mild infection followed by immunity. In this connection I should like to mention briefly some recent experiments of Dr. James R. Dawson, Jr.,¹⁹ at Vanderbilt, with the virus of rabies.

Dr. Dawson has succeeded in infecting the brains of chick embryos with several strains of rabies virus, including a street virus, a fixed virus and a strain derived from human infection. After being passed through several generations by successive intracerebral inoculations of chick embryos with infected brain, the street virus was injected by the intracerebral route into rabbits. All of 19 rabbits thus inoculated developed acute encephalitis with fever and a peculiar weakness and incoordination of the muscles, especially those of the neck. Thirteen of the 19 recovered, and 4 of these selected at random were completely immune to a heavy intracerebral dose of street virus, while 2 controls that received one hundredth as much rapidly succumbed with rabies.

This, I believe, is the first time a strain of rabies virus has been so modified that it would induce an immunizing and self-limited acute encephalitis in any animal species. A similar alteration of virulence for the dog would very likely be of great practical importance in the control of this distressing disease, but the strain so altered in virulence for rabbits is still fatal for dogs, at least in large doses, although Dr. Dawson is hopeful of inducing further modification that will be of help.

In conclusion, I should like to reiterate my main thesis that a knowledge of pathogenesis of virus diseases is necessary to a complete understanding of immunity. The patterns of pathogenesis of these diseases are determined by the cell-virus relation, which depends on the requirement by the virus of the internal medium of living susceptible cells for multiplication. The portal of entry, the primary lesion and the dissemination and elimination of each virus depend on the accessibility of certain susceptible cells in each case.

Although the mechanism of immunity is not yet well understood, experimental investigations indicate that, in at least most cases, humoral antibodies are very important factors, although their presence does not always indicate immunity or explain its phenomena. It has not yet been proved that susceptible cells themselves can actively participate in creating the resistant state, although their role is not known. Immunity does not depend entirely on a state that prevents virus from entering susceptible cells. Immunity is relative, and with certain infections of man partial immunity will modify the clinical features of the disease.

HYDRONEPHROSIS STANDARDIZATION OF SURGICAL TREATMENT*

THOMAS E. GIBSON, M.D.

SAN FRANCISCO, CALIFORNIA

REFERENCE to the voluminous literature on hydronephrosis reveals a renewed interest in the last decade in the problem of ureteropelvic obstruction and its surgical correction. The historical aspect of this problem has been reviewed in detail by Mathe¹. Trendelenburg² is given credit for the first attempt at plastic repair in 1886, but his effort proved unsuccessful owing to death of the patient from intestinal obstruction. In 1891 Kuster³ reported the first successful plastic operation on the renal pelvis. His operation consisted in reimplantation of the excised ureter in the pelvis at its most dependent part. One year later, Fenger⁴ described a plastic operative procedure that he had done for the relief of hydronephrosis due to valve formation and stricture of the ureter. This consisted in longitudinal incision at the point of obstruction, with transverse closure, an adaptation of the Heineke-Mikulicz principle used in intestinal surgery. Study of the many types of plastic procedures subsequently applied to the correction of ureteropelvic obstruction shows a fairly close parallelism to methods that have become more or less standard in gastrointestinal surgery. The stimulus of this early work led to an era in which the renal pelvis became the recipient of surgical attention that was perhaps more enthusiastic than discriminating. There were many failures, and even those cases in which the results were termed successful must be accepted with reservation, since they antedated the

development of urography with its present-day precision in the evaluation of surgical end results. Even at the present day, no one is justified in citing an end result as successful without the evidence of urography after a sufficient postoperative period has elapsed. Silent destruction of the kidney may occur postoperatively and give a false impression of cure unless checked by careful urological investigation.

That the earlier enthusiasm for conservative plastic surgery waned or fell into disfavor is evident from a review of the discussion of hydronephrosis that occurred at the German Urological Congress in Vienna in 1921, where the fact was disclosed that up to that time nephrectomy was the generally accepted operation for hydronephrosis. Since then there has been a gradual recrudescence of interest in conservative plastic surgery, which received a real impetus in the symposium on hydronephrosis participated in by Von Lichtenberg, Walters, Quinby and others at the annual meeting of the American Medical Association in 1929. Reference to the symposium on hydronephrosis of the American Urological Association at Minneapolis in 1937 furnishes a good cross-section of the progress that has been made in the last decade, and other noteworthy contributions in the last few years have served to establish the plastic surgery of ureteropelvic obstructions on a firm foundation.

However, in spite of this progress it is still the common practice to perform nephrectomy on many

*Read at a meeting of the New England Branch of the American Urological Association, Boston, February 15, 1940.

hydronephrotic kidneys that might have been saved by plastic surgery. Reasons for this unfortunate state of affairs, as enumerated by Ormond,⁸ are unfamiliarity on the part of the profession with the methods that can be employed, lack of confidence in plastic operations as a remedy for hydronephrosis, and lack of agreement as to the

renal Trendelenburg operation, and is similar to the Finney pyloroplasty. Von Lichtenberg's operation is a variation of the same fundamental principle. In the presence of a vascular band containing an artery too large to sacrifice with safety, Young's⁶ plastic procedure may occasionally be applicable, although most surgeons have surmounted this prob-

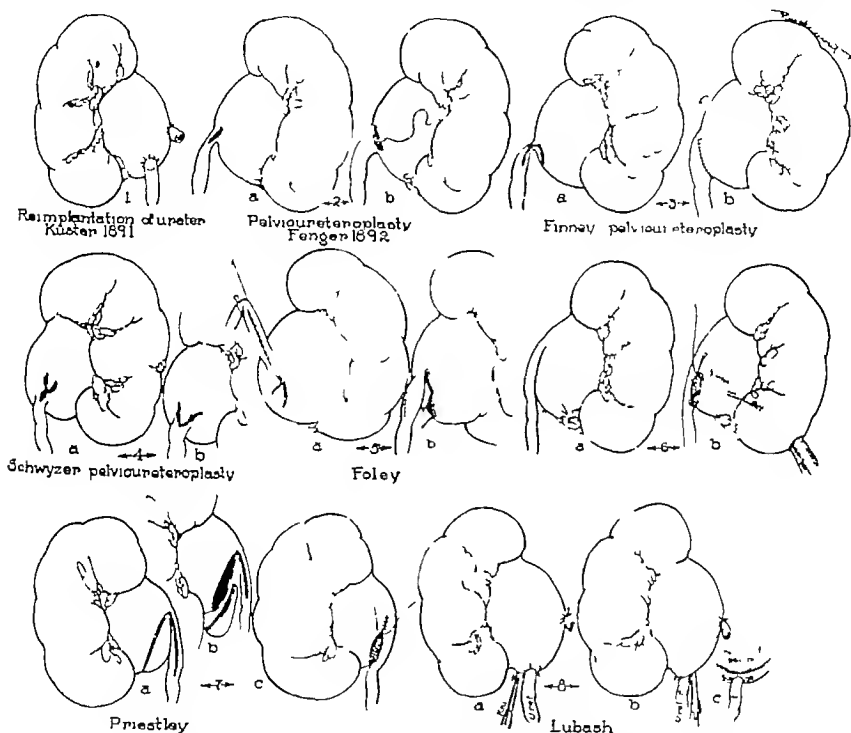

FIGURE 1 Sketches illustrating the Main Types of Pyeloureteroplasty Now in Vogue

preferable type of operation and lack of standardization of procedure.

In the surgical correction of ureteropelvic obstruction, four basic methods have been oftenest used (Fig 1). These are as follows: reimplantation of the excised ureter in the pelvis at its most dependent part (Küster), longitudinal incision, with transverse closure (Fenger), the Y incision with the V closure (Schwyzer, Foley), and some type of lateral anastomosis, either with the pelvis or another portion of the ureter (Trendelenburg, Priestley).

The fourth type of repair is essentially the orig-

inal Trendelenburg operation, and is similar to the Finney pyloroplasty. Von Lichtenberg's operation is a variation of the same fundamental principle.

In the presence of a vascular band containing an artery too large to sacrifice with safety, Young's⁶ plastic procedure may occasionally be applicable, although most surgeons have surmounted this problem by the first method enumerated above. Figure 2 shows my modification of the Fenger operation.

A study of the literature reveals that no one of the methods used in the past has been an unqualified success. Statistical reviews of end results of plastic operations in the more recent series reported indicate failure in anywhere from 15 to 33 per cent of cases.

Reasons for failure are enumerated by Lubash⁷ as follows: leakage of urine and perirenal infection at the point of anastomosis, tension along the suture line with secondary infection, puckering

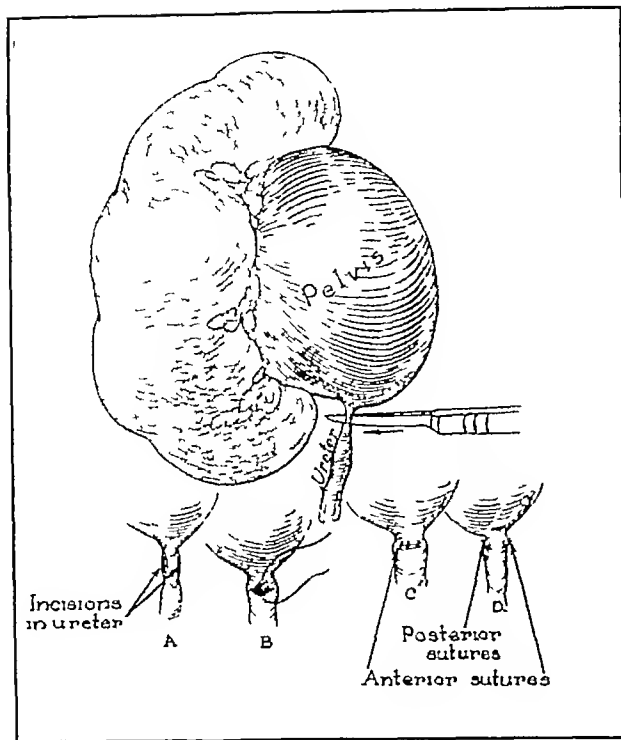

FIGURE 2 Drawing Illustrating the Author's Modification of the Fenger Operation

A Bard-Parker No 11 blade is used to transfix the strictured area at the ureteropelvic junction. This might be termed a double Fenger operation. It is suited to Type I hydronephrosis, but as a rule the Rammstedt procedure is preferred because of its simplicity, and the facts that incision is not made into the lumen of the ureter and that no suturing is necessary

and buckling at the line of anastomosis, new stricture formation, acting as a boomerang, retention of urine and secondary pyelonephritis or cortical abscess formation, and persistent urinary fistula.

It is evident that the present methods of surgical treatment of hydronephrosis leave much to be desired, and it is therefore appropriate at this time to take an active interest in the problem of saving hydronephrotic kidneys from nephrectomy or ultimate destruction through unsuccessful plastic surgery. I believe that there are still more fundamental reasons for failure which have not previously been sufficiently stressed, and that more uniform success will follow the adherence to two simple types of surgical procedure adapted to the two main types of hydronephrosis.

Obstructions at the ureteropelvic outlet fall naturally into two main groups (Fig 3). Type I, stricture of the ureteropelvic junction, and Type II, valve formation caused by high insertion of the ureter into the pelvis.

Both types are frequently complicated by extrinsic factors such as compression or kinking at the ureteropelvic juncture caused by bands, either fibrous or vascular, by ptosis or by adhesions, either inflammatory or congenital. Figures 4 to 9 show the successive steps of the two operations which in my experience are best adapted to these two types of hydronephrosis. The first necessity is, of course, the removal of all obstructing bands and adhesions, in other words, a thorough pyelo-

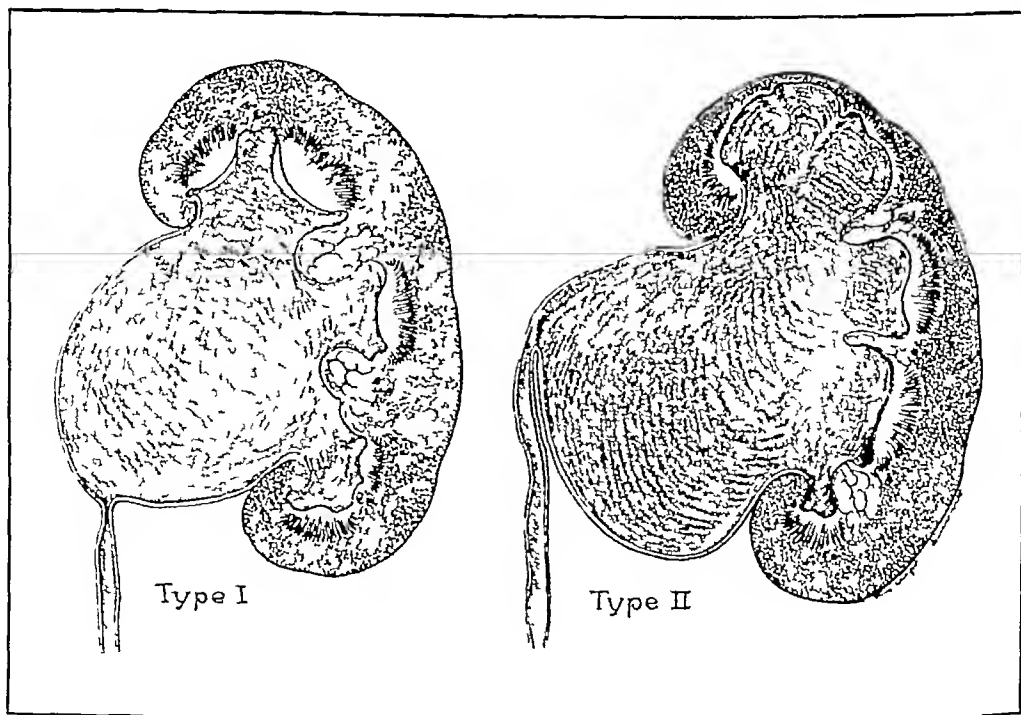

FIGURE 3 Drawings Illustrating the Two Main Groups into Which All Cases of Hydronephrosis Fall

Type I—stricture of the ureteropelvic junction

Type II—high insertion of the ureter with angulation and valve formation

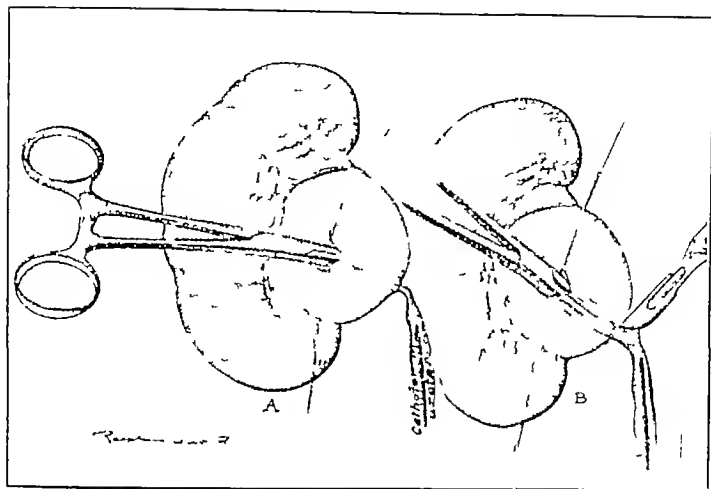

FIGURE 4 Operation for Type I Hydronephrosis

These drawings and those in Figures 5 and 6 illustrate the technic of the operation. Through a pyelotomy incision the strictured ureteropelvic junction is dilated with a hemostat and externally several parallel vertical incisions are made down to the mucosa as in the Ranstedt operation.

ureterolysis. This is followed by one or the other operation, depending on whether the hydronephrosis is Type I or Type II. In either case no

sutures are used, and the ureteropelvic opening is maintained by adequate splinting and nephrostomy drainage, the most important single element in obtaining a successful result. I should not eschew the use of sutures entirely, but wish particularly to emphasize the relative importance of splinting. No matter how generous the surgeon is in the use of sutures in plastic repair, the outcome is likely to be a failure unless he makes use of splinting; conversely, if he places his dependence on adequate splinting the result will almost certainly be successful even though he uses no sutures at all. The value of the ureteral splint has been emphasized by Peck,⁸ and later by Harris,⁹ Cabot,¹⁰ Moore,¹¹ Sargent,¹² Priestley,¹³ and others, but has not received the attention it deserves. It should be maintained in situ post-operatively for ten days to three weeks or even longer, depending on the extent of deformity and infection. It is hardly necessary to state that infection should be eliminated, so far as possible, by preoperative treatment. If ptosis is present, nephropexy should be included in the operative treatment. In the occasional case of slight hydronephrosis of a possible dynamic nature where mechanical obstruction is not a clear-cut factor, I have also performed renal sympathectomy in order to make doubly sure of relieving the patient of pain. In other cases that do not run quite true to type additional measures, such as excision of a portion

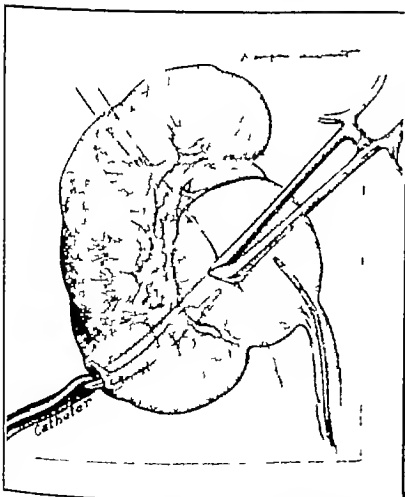

FIGURE 5 Operation for Type I Hydronephrosis

The point of the hemostat is pushed out through the lower major calyx and a double-eye Robinson catheter No. 18 or 20 Fr. is pulled into the pelvis.

of the hydronephrotic pelvis where it is excessively redundant, may be indicated

The procedures here advocated are characterized by their simplicity and the ease and speed with which they can be performed. Difficult technical practices and complicated methods of suture

The following report will serve to illustrate my point

G C, a 25-year-old woman, had a congenital solitary left kidney with advanced hydronephrosis. She entered the hospital in an almost moribund condition, due to acute fulminating pyelonephritis with fever, nausea and

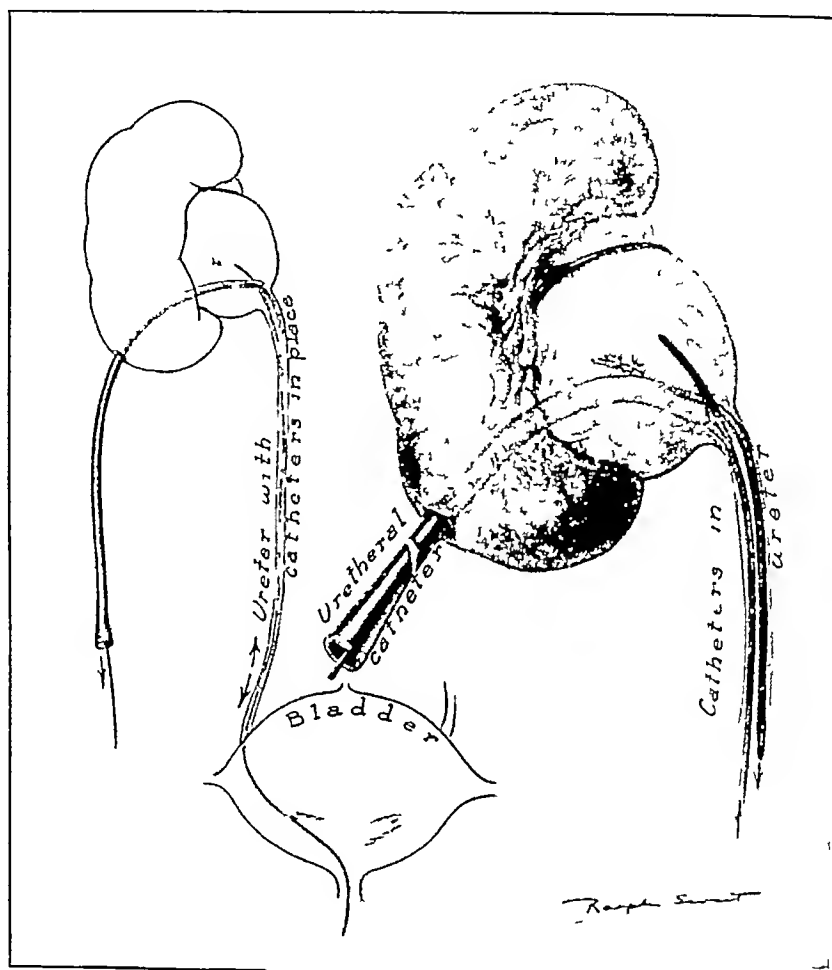

FIGURE 6 Operation for Type I Hydronephrosis

These show the conclusion of the operation, with the method of nephrostomy drainage and ureteral splinting. Prior to operation a No 7 Fr ureteral catheter is passed to the kidney through the cystoscope. After the Robinson urethral catheter is drawn into the pelvis a second No 7 Fr ureteral catheter is passed in through the Robinson catheter, emerging from one of the openings, and is passed down the ureter along side the ureteral catheter already in place. This provides adequately for two-way drainage and irrigation of the pelvis, and doubly splints the ureter.

are entirely eliminated. One may well question the value of sutures in the attenuated tissues of the hydronephrotic pelvis complicated by the presence of urine and more or less infection. In those cases of elaborate plastic operation and delicate suturing in which the outcome has been favorable, the result may well be attributed to the adequate use of splinting rather than to the plastic procedure itself.

vomiting, and repeated chills. A No 7 Fr whistle tip ureteral catheter was successfully passed cystoscopically to the kidney pelvis and was left in place for drainage. There was moderate improvement, with the aid of repeated clyses and urinary antiseptics, but on the whole the course was stormy for the next 2 weeks, with the temperature never normal. Eventually it became impossible to get a catheter back through the obstruction at the ureteropelvic junction after it had become displaced, and the patient promptly lapsed into her original almost moribund state, with high fever and chills.

An emergency operation was performed with the sole purpose of providing nephrostomy drainage with all possible dispatch because of the patient's precarious condition. The kidney was quite large, grayish soft and flabby and the cortex was spotted with innumerable small whitish abscesses the size of pinheads. The perirenal and peripelvic tissues were very edematous and friable, and easily dissected away permitting an excellent view of the pelvis and ureteropelvic outlet. The condition proved to be a characteristic Type II hydronephrosis with high insertion of the ureter and an obstructing vascular band contain-

ing a retrograde pyelogram before operation, while Figure 10B shows an excretion urogram demonstrating the condition of this solitary kidney 6 months later. The urine was sterile on culture and free from pus cells. A phenolsulfonephthalein test showed an output of 60 per cent in 2 hours. Three years later the patient wrote that she had remained perfectly well.

COMMENT

The ultimate result of the preliminary drainage operation in this case was so satisfactory that a secondary plastic operation appeared to be entirely unnecessary. This experience presented considerable food for thought and raised a question as to the rationale of the plastic operations on hydronephrosis that are in general use at the present time. I question the necessity for complicated plastic procedures with elaborate suturing, which are more or less time-consuming, and one questions how well such sutures hold in the attenuated and devitalized tissues of the obstructed pelvis in the presence of urine and varying degrees of infection. I reiterate that reliance on adequate splinting rather than sutures will give a higher percentage of successful end results. An orthopedist would not think of reducing a fracture without a splint to hold it in proper alignment during the healing process. This orthopedic principle can be borrowed by the urologist to good advantage. McArthur¹⁴ has shown that the splint can be successfully used to bridge a hiatus in the ureter where there has been an interruption of its continuity and J¹⁵ have stressed the value of the ureteral splint following removal of calculi from the kidney pelvis or upper ureter which is obstructed or distorted and kinked by dense adhesions. It may occasionally be advantageous to use sutures in conjunction with splinting, but they are of secondary importance and should be employed sparingly, and one should meticulously approximate the cut edges, avoiding puncture of the mucosa if possible. No 00000 chromic catgut appears to be the most suitable material for plastic work.

Judgment in the selection of cases for plastic operation deserves a word of comment. Functional tests conducted preoperatively are generally misleading, as well shown by Schulhof and Cabot.¹⁶ Even in the presence of a normal mate, nephrectomy should never be decided on unless the kidney has been actually viewed at operation and found to be only a thin walled sac without an appreciable amount of parenchyma, or unless infection has destroyed the parenchyma beyond hope of recovery. Preoperative functional tests may indicate more or less complete functional impairment, yet at operation a considerable amount of normal looking parenchyma may be found which will surprise one with the degree of functional resto-

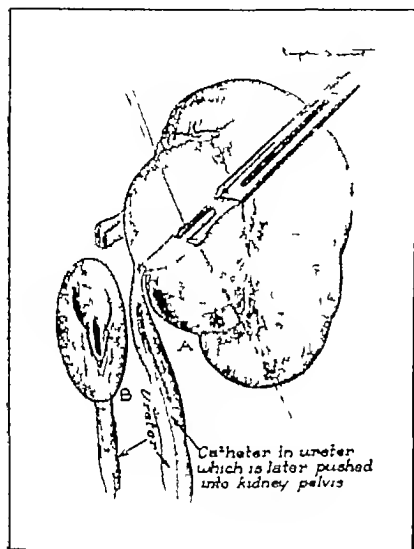

FIGURE 7 Operation for Type II Hydronephrosis

This drawing and that in Figure 8 illustrate the technique of the operation. A No. 7 Fr. ureteral catheter is passed up the ureter prior to operation. A pyelotomy incision is made and the valve-like partition caused by the high insertion is incised downward with scalpel or scissors as far as necessary to provide a wide opening at the ureteropelvic junction with dependent drainage. The end of the catheter if not already in the pelvis is advanced until it is well within

ing a rather large vein. The band was quickly resected, the pelvis opened and ureteropelvic junction incised downward. Nephrostomy drainage and ureteral splinting (as in the Type II operation) concluded the operative procedure. No sutures were used first because of the need for haste, and secondly because the tissues were too soft and friable to hold a suture. My plan was first to provide nephrostomy drainage, and if the patient did not succumb to perform some sort of plastic operation at a later date.

Immediately following operation the patient began to improve. The nephrostomy drainage and splinting were maintained for 3 weeks. After removal there was no leakage of urine through the wound which promptly healed, and the patient made a rapid recovery. Figure

ration that will occur following a successful plastic operation, even in the presence of a normal mate

This paper has been purposely limited to the discussion of non-calculous obstructions at the ureteropelvic juncture. It should not be necessary to emphasize that hydronephrosis may be due to

form of bands, adhesions, anomalous vessels, ptosis and so forth, as previously enumerated. Extrinsic factors may alone cause hydronephrosis, and their removal will result in cure without the necessity for plastic operation in the absence of intrinsic factors

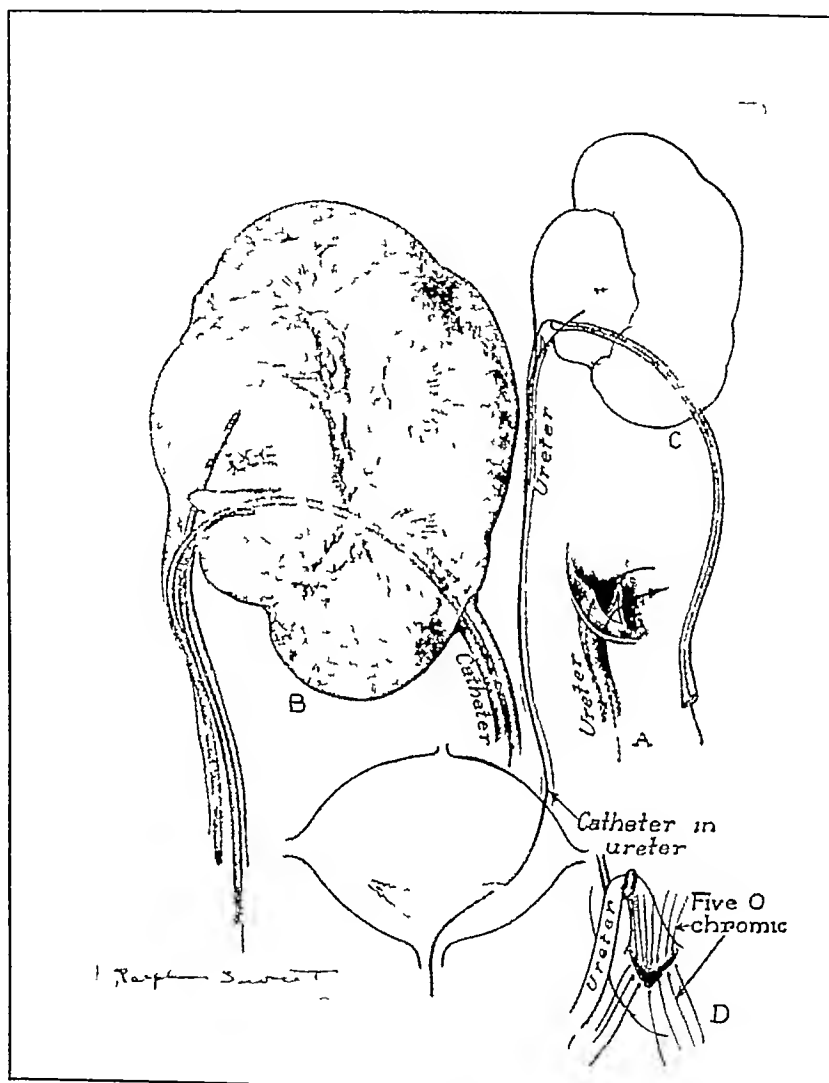

FIGURE 8 Operation for Type II Hydronephrosis

This drawing illustrates the method of nephrostomy drainage and double ureteral splinting, which is the same as in the Type I operation. The entire procedure is easily and quickly performed. No sutures need be used except to close the pyelotomy incision, and even these can be dispensed with. Nephrostomy drainage is preferable to pyelostomy drainage because the renal parenchyma splints the tubes and maintains them in accurate position with a greater degree of certainty. Sutures as shown in D are optional.

a great variety of obstructions at any point below the level of the renal pelvis, even to the external urethral meatus, and that accurate differential diagnosis requires their elimination before resorting to plastic surgery on the ureteropelvic juncture.

Types I and II hydronephrosis may be properly termed intrinsic types. They are usually complicated by one or more extrinsic factors in the

The question arises as to whether hydronephrosis due to obstruction at the ureteropelvic juncture can ever be relieved by cystoscopic dilatations. Rarely, Type I hydronephrosis can be relieved in this way, provided there are no complicating extrinsic factors, but most of the cases will require surgical relief.

A more general comprehension of the fact that

the vast majority of cases of hydronephrosis fall into two groups or types, susceptible to correction with a fair degree of certainty by one or the other of two simple types of operation should result in fewer nephrectomies and in a higher per-

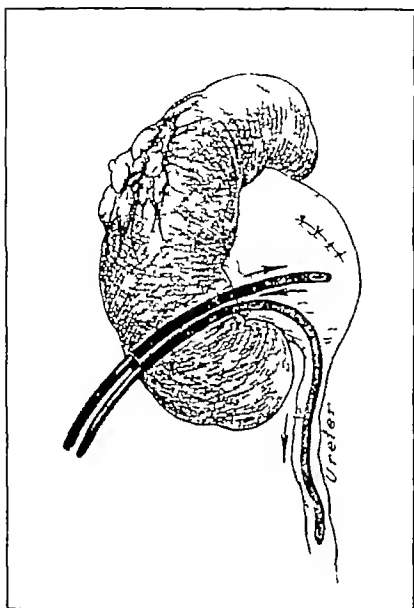

FIGURE 9 An Alternative Method of Nephrostomy Drainage and Ureteral Splinting

Following the necessary plastic procedure two small Robinson urethral catheters No. 10 or 12 Fr may be drawn into the pelvis and one passed down the ureter safely beyond the point of obstruction. Additional openings are made in these catheters at strategic points as shown in the sketch

centage of successful end results in the plastic repair of hydronephrosis.

CONCLUSIONS

The present status of the surgical treatment of hydronephrosis is briefly reviewed. Nephrectomy is still too often resorted to because of lack of confidence in plastic operations. The principal types of plastic operations in current usage are described and illustrated. Statistical summaries of end results show a relatively high percentage of failures, and point to the necessity for a re-evaluation of the types of hydronephrosis and standardization of methods of surgical treatment.

Hydronephrosis due to ureteropelvic obstruction

falls into two general groups, described as Types I and II

Two operative procedures are proposed, which seem best adapted to the surgical treatment of hydronephrosis. They are characterized by simplicity and ease of performance, with emphasis on the necessity for nephrostomy drainage and ureteral splinting, with elimination of sutures

Experience with these procedures suggests the possibility of eliminating elaborate plastic operations and the delicate suturing that they entail, in favor of simpler procedures which will decrease the number of nephrectomies for hydronephrosis and give greater assurance of successful end results

DISCUSSION

DR. CLYDE L. DEXING, New Haven, Connecticut: I have for a long time been looking at hydronephrosis simply from an operative standpoint. In 1925 or 1926 I reimplanted a ureter in the wife of a young doctor friend of mine. He was not a urologist but a surgeon, and he knew quite a bit about surgery of the kidney. The morning after the operation Dr. Quinby published a paper in which he asserted that this operation should never be performed. Fortunately however this case proved to be one of the most successful I had ever treated. I encountered a large cystic mass at the point of anastomosis. The patient had had frequent urinautions since childhood and had been through one pregnancy. She has remained free from infection.

There is nothing more intriguing to me than the correction of hydronephrosis, and I am indebted to Dr. Gibson in reducing this treatment to logical terms and rendering it both simple and efficacious.

DR SAMUEL N VOSE, Boston Dr Gibson's operations seem logical I have used the Rammstedt operation with satisfaction I have employed for a splint, with satisfactory results, a single catheter in the cortex, with holes cut corresponding to the pelvis

I should like to mention the significance of minor degrees of hydronephrosis as regards pain and a predisposition to infection and stone formation Compensation has been widely recognized Compensated bladders carry a good deal less residual urine in the presence of bladder-neck obstruction than do decompensated ones The same thing applies to the kidney pelvis In the presence of a good deal of obstruction, extrarenal pelvis usually show extensive hydronephrosis, while in the intrarenal pelvis the kidney cortex is more apt to suffer

DR GIBSON (closing) It may be that we need a hydronephrosis registry, as we need a carcinoma registry, in order properly to evaluate and standardize the operations for plastic repair of hydronephrosis I have been appalled at seeing many doctors, not only general surgeons but also urologists, remove fairly good kidneys capable of a marked amount of functional restitution rather than attempt a plastic operation, because they lacked confidence in it. Certainly if one lacks confidence one is inclined to do a nephrectomy, because if a plastic operation is not successful the patient may require a second operation involving nephrectomy, which does not redound to the credit of the surgeon. Appraisal of results attendant on adherence to the principles of plastic repair above outlined limits the indications for nephrectomy to those kidneys which are hopelessly destroyed

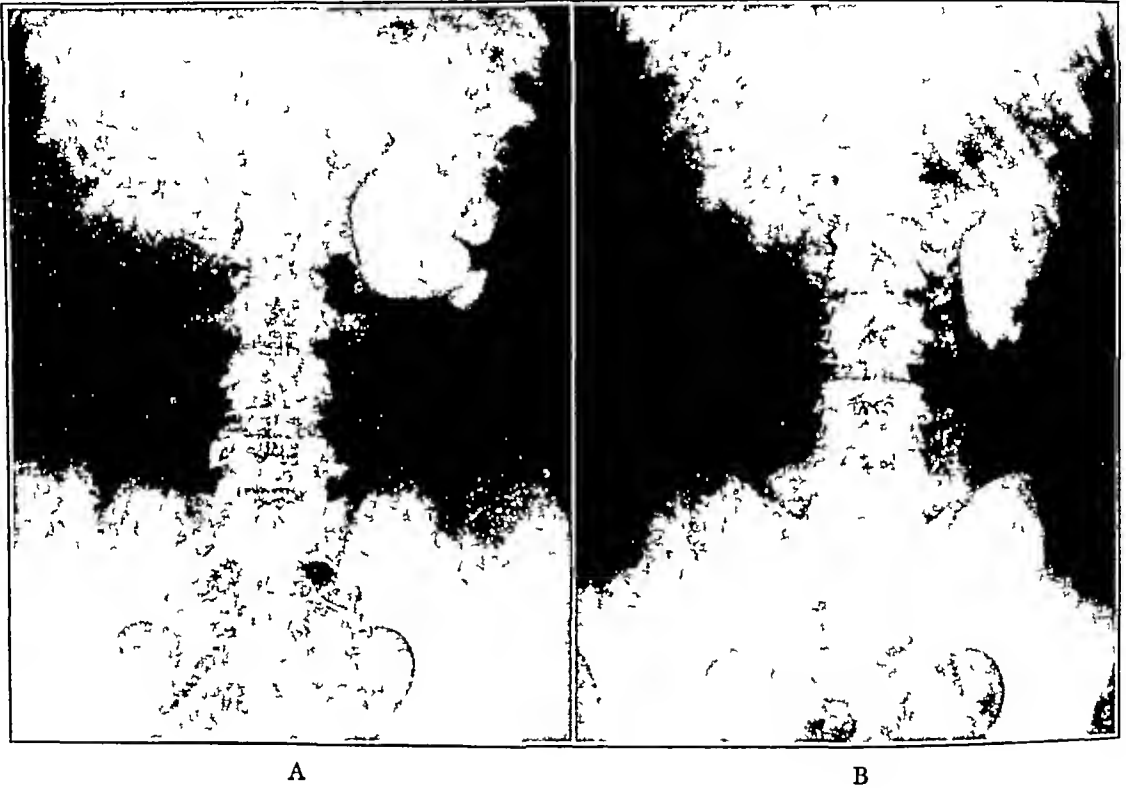

FIGURE 10 Results of Operation

A—photograph of retrograde pyelogram in a twenty-five-year old woman, with a Type II hydronephrosis of a congenital solitary left kidney complicated by acute pyelonephritis B—photograph of excretion urogram six months after operation There were excellent restoration of function, complete elimination of infection and adequate dependent drainage

DR HENRY H COLBY, Boston Dr Gibson has made The successes I have had in pelvic junction have been the ureter or with the I no success with the ly because I do not know Can Dr Gibson discuss the How is one to tell when engaged and its mate has taken I also like to know how much still do a successful plastic I should like to ask interred sloughing of the operation

Dr Colby spoke of reimplantation In the original Küster operation the ureter is resected and reimplanted in the most dependent portion of the pelvis. The only case in which this procedure is followed is that of an anomalous vessel, an artery that is too large to sacrifice safely This does not occur very often Here also the key to success is adequate splinting and nephrostomy drainage. I have not seen any sloughing of the mucosa as a result of splinting

It has been asked, In the presence of how much infection should one attempt a plastic operation? Of course, one should try to clear up infection prior to operation, but I should not hesitate to operate in the presence of considerable infection, relying on ureteral splinting and nephrostomy drainage

APPENDICES EPIPLOICAE*

GEORGE A. MOORE, M.D.†

BROCKTON, MASSACHUSETTS

THE early literature regarding appendices epiploicae has been reviewed in considerable detail by several writers in the past two decades, notably Hunt,¹ Klingenstein² and Patterson.³ Only a very brief summary therefore will be given here of the more important contributions to this subject in the past.

In 1703 Littre⁴ discovered a pea sized foreign body in the abdominal cavity that was thought to be the remains of an appendix epiploica. Cruveilhier⁵ (1849) and Deville⁶ (1851) also described foreign bodies in the abdominal cavity, which were assumed to have a similar origin.

In 1863 Virchow⁷ gave a detailed description of the formation and composition of foreign bodies in the abdomen and claimed that the majority had their origins in appendices epiploicae.

In 1905 Ruedel⁸ published the first comprehensive study of the clinical aspects of 8 cases illustrating the various pathologic conditions associated with appendices epiploicae.

Robinson's⁹ thesis, published in 1908, on the anatomy and pathology of the "seroappendices," is the most painstaking study of the subject that has yet appeared. He stated that the dog, cat, rabbit and rat have no seroappendices, but that the anthropoid ape has seroappendices similar to those found in man. Contrary to other writers, he stated that the appendices are found in the fetus at two and three months, as well as in the newborn. Robinson's detailed description of the anatomy, physiology and pathology of appendices epiploicae is still generally accepted.

Anatomically appendices epiploicae are pedunculated tabs of fat attached to the colon, covered only with peritoneum, which vary greatly in size, shape and number. They extend from the cecum to the rectum, usually in two rows, one in relation to the anterior tenia and the other in relation to the posterior internal tenia. The largest appendices are usually found on the sigmoid. They are true hernias of the visceral peritoneum, filled with fat.

The physiological function of appendices epiploicae has never been definitely established. Robinson⁹ has suggested that they are a factor in the movements of fluids in the colon.

The pathologic conditions which involve appendices epiploicae and the approximate number of

times they have been reported are as follows: foreign bodies, 15; intra abdominal torsion, 43; intra hernial torsion and strangulation, 15; intrahernial incarceration, 16; and adhesions resulting in intestinal obstruction, 7. As additions to these I submit herewith 2 cases of intra abdominal torsion, 1 case of adhesion incarceration in a hernial sac, causing strangulation of a loop of the sigmoid, and 2 cases of intra abdominal adhesions resulting in acute intestinal obstruction.

Foreign bodies which lie in the abdominal cavity or in a hernial sac originate in most cases from gradual torsion of appendices epiploicae and give rise to no symptoms. It is quite probable that most cases of acute torsion require early operative relief and hence do not result in the formation of foreign bodies. In Virchow's⁷ case, death resulted from peritonitis apparently from a foreign body originating in an appendix epiploica attached to the vermiform appendix. Ruedel⁸ cited a case with symptoms of "gall-bladder adhesions" in which only fatty foreign bodies were found. He also described a patient with abdominal pain from a hernia, who was relieved by removal of a small, fatty foreign body from the hernial sac. The potential danger of infection from any foreign body in the abdomen is generally recognized.

Torsion occurs more frequently than any other pathologic process in appendices epiploicae. Chronic and acute types of torsion are found at operation, the acute torsion is more frequently observed, as it is commonly accompanied by urgent symptoms which necessitate operation.

The chronic type is probably the cause of many foreign bodies in which a gradual saponification of the fat content has occurred, followed by calcification or the formation of pseudo-cartilaginous bodies. Chronic torsion is the cause of certain types of adhesions producing intestinal obstruction, which will be described later. It is quite probable that a certain number of cases with unexplained mild attacks of abdominal pain are due to chronic torsion of an appendix, which terminates in a foreign body or adhesions.

Many patients in whom acute torsion is found at operation give a history of numerous attacks of abdominal pain in the past. Cases of torsion have been reported (Huot¹⁰) in which no history of acute symptoms was obtained and the strangulated appendix epiploica was an incidental finding at operation. In most patients, however, there

*Read by title at the annual meeting of the New England Surgical Society, Boston, Massachusetts, September 29-30, 1939.
†Sargeant, Moore Hospital, Brockton, Massachusetts.

DR SAMUEL N VOSE, Boston Dr Gibson's operations seem logical I have used the Rammstedt operation with satisfaction I have employed for a splint, with satisfactory results, a single catheter in the cortex, with holes cut corresponding to the pelvis

I should like to mention the significance of minor degrees of hydronephrosis as regards pain and a predisposition to infection and stone formation Compensation has been widely recognized Compensated bladders carry a good deal less residual urine in the presence of bladder-neck obstruction than do decompensated ones The same thing applies to the kidney pelvis In the presence of a good deal of obstruction, extrarenal pelvis usually show extensive hydronephrosis, while in the intrarenal pelvis the kidney cortex is more apt to suffer

DR. GIBSON (closing) It may be that we need a hydronephrosis registry, as we need a carcinoma registry, in order properly to evaluate and standardize the operations for plastic repair of hydronephrosis I have been appalled at seeing many doctors, not only general surgeons but also urologists, remove fairly good kidneys capable of a marked amount of functional restitution rather than attempt a plastic operation, because they lacked confidence in it. Certainly if one lacks confidence one is inclined to do a nephrectomy, because if a plastic operation is not successful the patient may require a second operation involving nephrectomy, which does not redound to the credit of the surgeon Appraisal of results attendant on adherence to the principles of plastic repair above outlined limits the indications for nephrectomy to those kidneys which are hopelessly destroyed

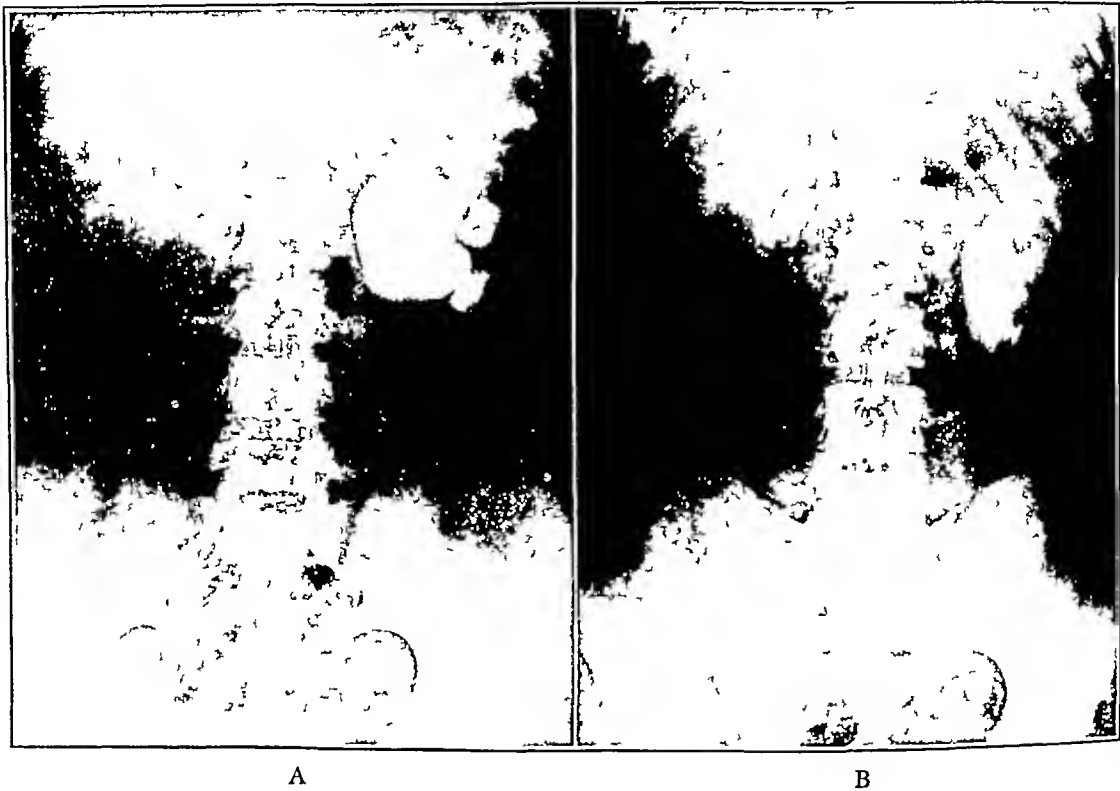

FIGURE 10 Results of Operation

A—photograph of retrograde pyelogram in a twenty-five-year-old woman, with a Type II hydronephrosis of a congenital solitary left kidney complicated by acute pyelonephritis B—photograph of excretion urogram six months after operation There were excellent restoration of function, complete elimination of infection and adequate dependent drainage

DR. HERBERT H. COLBY, Boston Dr Gibson has made The successes I have had in the pelvic junction have been the ureter or with the I no success with the ly because I do not know an Dr Gibson discuss the How is one to tell when aged and its mate has taken also like to know how much still do a successful plastic I should like to ask interred sloughing of the operation

Dr Colby spoke of reimplantation In the original Küster operation the ureter is resected and reimplanted in the most dependent portion of the pelvis. The only case in which this procedure is followed is that of an anomalous vessel, an artery that is too large to sacrifice safely This does not occur very often Here also the key to success is adequate splinting and nephrostomy drainage. I have not seen any sloughing of the mucosa as a result of splinting It has been asked, In the presence of how much infection should one attempt a plastic operation? Of course, one should try to clear up infection prior to operation, but I should not hesitate to operate in the presence of considerable infection, relying on ureteral splinting and nephrostomy drainage

testinal obstruction. Whether the inflammation is preceded by torsion has not been determined. In certain cases, torsion is definitely the cause, as it is found that the appendix has dropped off, that the proximal stump has adhered to the parietal peritoneum, mesentery or intestine, and that a loop of intestine has slipped in back of the cord thus formed and has thus become strangulated. In one of my patients (Case 5) fully a third of the small intestine was strangulated in this way. The other two processes causing obstruction are adherence of an appendix epiploica to the parietal peritoneum or viscera and adherence of two inflamed appendices across a loop of intestine. Baumeister, Hargens and Morsman¹⁶ collected 6 cases of intestinal obstruction from the literature, and added 1 to the list. The following 2 cases occurred in my practice, bringing the total number to 9.

CASE 4 M. A. P. (No. 7543) a 75-year-old married woman, entered the Moore Hospital Brockton Massachusetts, on May 3 1933. She had had a total hysterectomy at another hospital in 1905. There had been no serious illness since operation, but she had been quite constipated in recent months. About 30 hours before admission she was seized with severe epigastric pain, nausea and vomiting and complained of marked tenderness in the left lower quadrant, which had persisted.

On physical examination the patient was of good color. The blood pressure was 124/90. The abdomen was moderately distended and extremely tender with spasm over the entire left side. The temperature was 97.6 F and the white-cell count 10,500. A flat x-ray plate of the abdomen and a barium enema showed evidence of small bowel obstruction.

At operation an appendix epiploica was found on the outer aspect of the descending colon. It was attached to the parietal peritoneum in the left flank. Beneath the band thus formed about 45 cm. of lower ileum was strangulated. When the band was severed the strangulated bowel appeared viable. Enterostomy was done above the site of the obstruction, which emptied the obstructed intestine. The patient appeared to be making a good recovery for 4 days and then developed pneumonia and died seven days after operation.

The discharge diagnoses were strangulation of a loop of ileum by a fibrous band resulting from an adhesion of an appendix epiploica to the parietal peritoneum in the left flank, and pneumonia.

CASE 5 P. W. (No. 8045) a 23-year-old unmarried woman entered the Moore Hospital Brockton Massachusetts, on April 17 1934. Her general health had been excellent in the past. The bowels were regular but the catamenia were irregular and accompanied by pain. About 5 months previously she had had an attack of epigastric pain, which was followed by a bowel movement which contained bright blood. Gastrointestinal x-ray films were taken, with inconclusive findings. Since then she had had two similar attacks. About 6 hours before admission,

while straining at stool she was seized with severe epigastric pain, nausea and vomiting. She became very pale, was faint, had a subnormal temperature and continued to vomit until she was admitted to the hospital.

On physical examination there was marked pallor. The skin was moderately cool. The blood pressure was 100/60. The temperature was 96.8 F., and the white cell count 11,000. The urine was normal. Nothing abnormal was found except moderate distention of the lower abdomen with tenderness in the left lower quadrant.

Following the usual preoperative therapy a left paramedian lower abdominal incision was made. Approximately a third to half the small intestine was strangulated by a taut small cord arising in the lower descending colon and attached to the base of the mesentery of the small intestine. No appendix epiploica was found at the distal end of this cord, but from its site of origin the latter was assumed to be a greatly stretched pedicle of an appendix epiploica. The band was excised, the strangulated intestine proved to be viable, and convalescence was uneventful.

The discharge diagnosis was strangulation of the small intestine by a fibrous band resulting from an adhesion of an appendix epiploica.

SUMMARY

It has been suggested by Patterson⁴ that diseases or better, pathologic conditions of appendices epiploicae occur more frequently than are reported in the literature. These conditions may well account for many cases of intestinal obstruction due to congenital bands of undetermined origin, and for certain cases explored for an acute abdominal episode in which no pathologic lesion is found.

An attempt has been made to emphasize some of the important facts in the literature regarding these uncommon lesions of appendices epiploicae, in the hope that a search will be made for them in acute abdominal conditions without obvious cause.

REPORT ON MEDICAL PROGRESS

PATHOLOGY

TRACY B MALLORY, M D *

BOSTON

HYPERTENSION AND RENAL DISEASE

THE CLOSE relation between renal disease and elevation of the arterial blood pressure has been common knowledge for three quarters of a century, but only within the last six years has convincing experimental evidence regarding the possible mechanism of this relation appeared. Through the intervening period innumerable clinical and anatomical studies served gradually to distinguish between the primary nephropathies with secondary elevation of the blood pressure and a syndrome which became known as "essential hypertension," in which high blood pressure preceded by long periods the development of any other clinical or functional evidence of renal impairment. Clinicopathological correlation, however, clearly demonstrated that very few of these patients at postmortem examination failed to show extensive arteriolar disease, particularly within the kidneys, though functionalist and morphologist futilely battled for decades over the precedence of the hypertension or the arteriolar degeneration.

Through the period from 1925 to 1935 pathological interest focused sharply on the details of the vascular lesions in nephrosclerosis and on their correlation with clinical types of hypertension. A "benign" and a "malignant" form were widely recognized, and exhaustive studies¹⁻⁶ of long series of cases were published affirming or denying the identity of the two types and the possibility of accurate clinicopathological correlation. The difficulties of histological distinction were attested by the considerable variation of the supposedly pathognomonic criteria, various authors emphasizing in turn periarterial granulomatous reactions,¹ necrotizing arteriolitis,³ endarteritis, alterative glomerulitis,⁵ and so forth as of pre-eminent importance, till the intricacies dazed even the professional morphologist.

In 1934 attention was suddenly shifted in a more profitable direction by the publication by Goldblatt and a group of associates⁶⁻¹⁶ of the first of a series of experiments on the production of hypertension and its physiological mechanism. If a clamp was placed on the renal artery which narrowed but did not occlude the latter, the systemic

blood pressure rose significantly for a period of weeks. If the clamp was removed or the ischemic kidney resected the blood pressure fell to the previous control level. The hypertension was therefore clearly dependent on the presence in the body of ischemic renal tissue. Bilateral narrowing of the renal arteries or unilateral narrowing with nephrectomy of the opposite sound kidney produced severe and apparently permanent hypertension. The experiments were quickly and widely confirmed,^{17, 18} and a wealth of investigation has been stimulated which may well prove to be only in its infancy. New methods of producing renal ischemia and consequent hypertension have been developed, such as exposure of the kidneys to x-rays (Hartman¹⁹) and enveloping them in a bag of cellophane (Page²⁰), which provokes the formation of a dense fibrous constricting capsule. Removal of the encapsulated kidney promptly brings the blood pressure back to normal, just as in the Goldblatt experiments.

It is clear that the nervous system is not directly responsible for the genesis of the hypertension, since renal denervation,^{21, 22} total sympathectomy²³ or total destruction of the spinal cord by pithing²⁴ does not prevent its development.

With a neural mechanism eliminated a humoral one seemed inescapable, and imaginations quickly turned to the possibility of the elaboration of pressor substances within the kidney. As far back as 1898 Tigerstedt and Bergman²⁵ had described a protein substance with a marked pressor action extractable from the renal cortex, which they named "renin." Forty years later, independently, but in quick succession, Landis, Montgomery and Sparkman,²⁶ Williams, Harrison and Mason²⁷ and Corcoran and Page²⁸ renewed these experiments and have obtained extracts with similar properties from the renal cortex. Since extracts of a great variety of tissues are known frequently to have depressor and occasionally pressor effects, the demonstration by Landis et al.²⁶ that this substance raises blood pressure without lowering skin temperature in contrast to all previously known pressor substances possibly extractable from tissues, such as adrenaline, pitressin, tyramine and so forth, is of fundamental importance. Confirmatory evidence that renin action is different from that of other pressor substances has been

*Assistant professor of pathology Harvard Medical School director Department of Pathology and Bacteriology Massachusetts General Hospital Boston

obtained by demonstrating the ineffectiveness of cocaine and other drugs either in increasing or decreasing its action.²⁹ Helmer and Page³⁰⁻³ have developed a method for producing renin in large amounts, and have been able to purify it and to show that renin itself in Ringer's solution has no pressor effect, but by interaction with a component of the blood serum (rather unfortunately called "renin activator") forms a third product designated angiotonin which appears to be the actual vasoconstrictive and pressor substance. Renin, they believe, is probably an enzyme since it is a protein, is thermolabile, reacts slowly with its substrate (renin activator) and is effective in small amounts in proportion to the substrate. Moreover, the renin angiotonin relation is a double one, since renin not only forms angiotonin but will with further contact destroy it. Whether or not the pressor effect of the presence of ischemic renal tissue in the body is dependent on an intact endocrine system is still somewhat uncertain. Hypophysectomy probably diminishes but does not abolish its effect.³¹ Bilateral adrenalectomy was found to abolish it, but the effect was cortical rather than medullary and the results with cortin and sodium substitution therapy have been variable.³²⁻³⁶

The application of this wealth of experimental data to human lesions is still far from clear. Excluding rare cases of chromaffin tumors of the adrenal medulla, it is doubtful if anyone to date has succeeded in isolating from the blood of hypertensive patients an effective pressor substance.³¹ Even in dogs the results are equivocal. Houssay and Fasciolo³⁷ report immediate elevation of the blood pressure following transplantation of an ischemic kidney into the neck of a nephrectomized dog, whereas the transplantation of a normal kidney had no such effect. Williams and Grossman³⁸ claim to have obtained renin and an adrenalin-like substance from the renal vein following perfusion of the isolated kidney. Yet Collins and Hoffbauer³⁹ were unable to demonstrate increased pressor action in blood from the renal vein of a hypertensive dog. Direct proof that renin formation and absorption are increased in the hypertensive individual, either human or canine, is still lacking. Tempting as the hypothesis is, it would be foolish at the present time to give it blind credence.

Moritz and Oldt,⁴⁰ reviewing the field of arteriolar sclerosis and hypertension, with advantage over previous investigators of following rather than preceding Goldblatt, have reported statistical data of great interest, based on a very careful comparison of 100 hypertensive with 100 non-

hypertensive individuals. Arteriolar sclerosis may of course be widespread throughout the body in both groups. In all organs and tissues but one the distribution was essentially similar in each, though naturally more severe and extensive in the hypertensive group. In the kidney, however, almost all hypertensive cases (97 per cent) showed renal arteriolar sclerosis in some degree, whereas in the control group only 12 per cent showed even mild arteriolar changes and only 2 per cent changes of moderate severity. These figures approximate closely those of previous investigators. The parallelism between hypertension and obliterative disease of the small renal vessels is impressive though not absolute. No comparable correlation could be found in the case of any other organ or tissue. The anatomical basis for renal ischemia was therefore present in the vast majority of the hypertensive patients and absent in an almost equal proportion of non-hypertensive patients. Even in the 3 cases of hypertension without arteriolar disease the possibility of renal ischemia existed, since severe atherosclerosis of the major vessels including the renal arteries and their main branches was present. It must be pointed out, however, that except in the case of major obliterative lesions the appearance of a vessel post mortem is not an altogether reliable index of its capacity during life.^{41, 42}

It is interesting in this connection that in Goldblatt's dogs the renal arterioles beyond the clamps do not undergo degeneration, whereas elsewhere in the body where the vessels are exposed to the increased intravascular tension arteriolar changes are widespread. Goldblatt has answered beyond doubt one question: prolonged hypertension will produce in the vessels exposed to it degenerative changes of types characteristic of human arteriolar lesions. By varying the degree of ischemia he could, in fact, vary at will the histologic reactions and produce either the hyalinization of benign sclerosis or the proliferative and necrotizing types of arteriolitis that have been widely considered to be typical of malignant hypertension. The latter appeared in his experience, only in animals in which the ischemia was so great that renal insufficiency developed. His findings give strong support to those who consider benign and malignant hypertension merely opposite poles of a single disease entity, as against those who consider them to be similar but pathogenetically different disorders.

Of great interest is the observation of Moritz and Oldt⁴⁰ that in 4 cases the arteriolar degeneration was limited to one kidney. The analogy to the Goldblatt kidney is arresting. Of very similar import is the description by Butler⁴³ of cases of

HYPERTENSION AND RENAL DISEASE

THE CLOSE relation between renal disease and elevation of the arterial blood pressure has been common knowledge for three quarters of a century, but only within the last six years has convincing experimental evidence regarding the possible mechanism of this relation appeared. Through the intervening period innumerable clinical and anatomical studies served gradually to distinguish between the primary nephropathies with secondary elevation of the blood pressure and a syndrome which became known as "essential hypertension," in which high blood pressure preceded by long periods the development of any other clinical or functional evidence of renal impairment. Clinicopathological correlation, however, clearly demonstrated that very few of these patients at postmortem examination failed to show extensive arteriolar disease, particularly within the kidneys, though functionalist and morphologist futilely battled for decades over the precedence of the hypertension or the arteriolar degeneration.

Through the period from 1925 to 1935 pathological interest focused sharply on the details of the vascular lesions in nephrosclerosis and on their correlation with clinical types of hypertension. A "benign" and a "malignant" form were widely recognized, and exhaustive studies¹⁻⁵ of long series of cases were published affirming or denying the identity of the two types and the possibility of accurate clinicopathological correlation. The difficulties of histological distinction were attested by the considerable variation of the supposedly pathognomonic criteria, various authors emphasizing in turn periarterial granulomatous reactions,¹ necrotizing arteriolitis,³ endarteritis, alterative glomerulitis,⁵ and so forth as of pre-eminent importance, till the intricacies dazed even the professional morphologist.

In 1934 attention was suddenly shifted in a more profitable direction by the publication by Goldblatt and a group of associates⁶⁻¹⁶ of the first of a series of experiments on the production of hypertension and its physiological mechanism. If a clamp was placed on the renal artery which narrowed but did not occlude the latter, the systemic

blood pressure rose significantly for a period of weeks. If the clamp was removed or the ischemic kidney resected the blood pressure fell to the previous control level. The hypertension was therefore clearly dependent on the presence in the body of ischemic renal tissue. Bilateral narrowing of the renal arteries or unilateral narrowing with nephrectomy of the opposite sound kidney produced severe and apparently permanent hypertension. The experiments were quickly and widely confirmed,^{17, 18} and a wealth of investigation has been stimulated which may well prove to be only in its infancy. New methods of producing renal ischemia and consequent hypertension have been developed, such as exposure of the kidneys to x-rays (Hartman¹⁹) and enveloping them in a bag of cellophane (Page²⁰), which provokes the formation of a dense fibrous constricting capsule. Removal of the encapsulated kidney promptly brings the blood pressure back to normal, just as in the Goldblatt experiments.

It is clear that the nervous system is not directly responsible for the genesis of the hypertension, since renal denervation,^{21, 22} total sympathectomy²³ or total destruction of the spinal cord by pithing²⁴ does not prevent its development.

With a neural mechanism eliminated a humoral one seemed inescapable, and imaginations quickly turned to the possibility of the elaboration of pressor substances within the kidney. As far back as 1898 Tigerstedt and Bergman²⁵ had described a protein substance with a marked pressor action extractable from the renal cortex, which they named "renin." Forty years later, independently, but in quick succession, Landis, Montgomery and Sparkman,²⁶ Williams, Harrison and Mason²⁷ and Corcoran and Page²⁸ renewed these experiments and have obtained extracts with similar properties from the renal cortex. Since extracts of a great variety of tissues are known frequently to have depressor and occasionally pressor effects, the demonstration by Landis et al.²⁴ that this substance raises blood pressure without lowering skin temperature in contrast to all previously known pressor substances possibly extractable from tissues, such as adrenaline, pitressin, tyramine and so forth, is of fundamental importance. Confirmatory evidence that renin action is different from that of other pressor substances has been

*Assistant professor of pathology Harvard Medical School, director Department of Pathology and Bacteriology Massachusetts General Hospital, Boston.

histologic picture of the nodes is fairly specific, with irregular 'star-shaped' abscesses, bordered by a zone of epithelioid cells and occasional giant cells. Plasma cells are apt to be very numerous in the remaining nodal tissue. Not infrequently the pathologist has been the first to suggest the correct diagnosis in cases which have been submitted to biopsy.

In women the course is quite different. Presumably because of primary involvement of a deeper lymphatic chain, inguinal node enlargement is rare. In contrast, hypertrophic or ulcerative elephantiasis of the labia or other portions of the pudenda (esthiomene) and inflammatory stricture of the rectum are the characteristic lesions. Any one of the three features or any combination can, however, occur in either sex. In contrast to the relative specificity of the histologic picture in the lymphadenitis, it is rare that anything but a non-specific reaction is reported in esthiomene or the rectal lesions. Marked plasma-cell infiltration is somewhat suggestive.

It was the development of the Frei test that first permitted the recognition of these three widely different clinical syndromes as manifestations of a single disease. Subsequently the virus has been repeatedly recovered and identified from cases of each type. The Frei test remains our most valuable diagnostic method. Antigen prepared from infected mouse brains has proved highly specific and more readily standardizable than human antigen, despite certain claims²¹ to the contrary. In competent hands a specificity and reliability approximating 95 per cent have been obtained.

Evidence is gradually accumulating that the disease does not necessarily remain localized. In the early stages generalized symptoms are frequent, and it is still uncertain to what extent they represent diffusion of the virus and to what extent they are systemic reactions to a localized infection. Of the latter type are probably the skin manifestations, both erythema multiforme and erythema nodosum, and the arthritides. Direct infection of the fallopian tubes has been reported by Schenken²² who has also recovered the virus from the brain of a human patient with symptoms of meningitis. Colonic lesions have been reported, and I have personally seen an isolated lesion of the sigmoid.

Certain observations of considerable interest have been recorded by Gsell.²³ In chronic cases, serum protein determinations frequently show a significant elevation (over 9 gm per 100 cc. in approximately half the cases), a rise caused almost wholly by elevation of the globulins. As would be expected under such circumstances, the formol

gel and Takata-Ara reactions are frequently positive. In a single bone marrow aspiration Gsell found so many plasma cells that a diagnosis of multiple myeloma was temporarily considered.

Finally, it is becoming increasingly apparent as recognition of the disease becomes more general and the Frei test is more extensively applied that the disease is world wide in distribution and much commoner than has generally been realized. Whether or not it is increasing cannot as yet be determined. Of its significant frequency in New England the reports of Howard and Strauss²⁴ and of Chapman and Hayden²⁵ bear witness.

CATARRHAL JAUNDICE

Interest in catarrhal jaundice has always been great in Scandinavia. It was Flindt,²⁶ an obscure Danish physician, who first challenged Virchow's hypothesis of a plug of mucoid inflammatory exudate in the common duct, and offered evidence that the disease was a specific infection and that the basic lesion was a diffuse hepatic degeneration. Forgotten for thirty years, it was rediscovered by Linstedt²⁷ and confirmed by Wallgren.²⁸ Since patients with catarrhal jaundice die only in the rare event that atrophy supervenes, knowledge of the early lesions has been derived from occasional biopsies of the liver usually consequent to a mistake in clinical diagnosis. Roholm and Iversen²⁹ have added considerably to this by a series of thirty-eight aspiration biopsies on 26 patients, obtained at intervals from the third to the fifty first day of the disease. In all cases they found poorly defined foci of liver-cell degeneration and necrosis, an inflammatory reaction predominantly mononuclear in character and varying proliferation of connective tissue—periportal, central and diffusely throughout the lobule. Though as a rule the hepatitis ran its course without leaving any other trace than a slight increase in connective tissue, in 3 cases the latter was marked enough to suggest cirrhosis. In 1 case, indistinguishable in its early stages from the others, a subacute atrophy developed.

A totally new suggestion as to the etiology of the disease has been offered by Andersen.³⁰ An epidemiological survey showed that in Denmark the incidence was lowest in Copenhagen and greatest in rural districts, particularly certain parts of Jutland where the chief economic activity is the raising of hogs. Hogs in Denmark frequently suffer from jaundice, and a fairly close parallelism was shown between the seasonal variation in the number of jaundiced hogs recorded at the slaughterhouses and the reported cases of human catarrhal jaundice. In a second paper Andersen³¹ re-

ports the appearance of jaundice in young pigs a few days after feeding them oil obtained by duodenal drainage from patients with catarrhal jaundice. The experiments still await confirmation. Perhaps it will appear with poetic justice from Germany, if an epidemic of catarrhal jaundice should follow the reported confiscation of the Danish hogs.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

CASE 26221

PRESENTATION OF CASE

A twenty-two-year-old white man was admitted to the hospital complaining of pain in the neck for five months.

Approximately five months before admission the patient began noticing sharp, shooting pains in the neck, usually occurring when he stooped for ward. These pains had apparently followed a gradually increasing stiffness of the neck which had progressed for two months before the pains appeared. He attributed these symptoms to a "cold" which had settled in his neck. Motion of the head and pressure over the cervical spine aggravated the discomfort. On one occasion with such movement, his neck snapped, and he became aware of acute pain so that he was forced to remain in bed to keep the head and neck at rest. A local physician who examined him diagnosed his ailment as arthritis. Two weeks later, because of a progression of symptoms, he was taken to an outside hospital where roentgenograms of the cervical spine were said to have shown "decay and destruction" of the cervical vertebrae. A plaster collar was applied, and he wore this constantly with complete relief of pain.

Two months before entry the right knee became painful, the pain radiating upward to the mid-thigh and perineum. The sacral and coccygeal regions, the right hip and the ilium became similarly painful a few weeks later.

Five weeks before admission he noticed beginning constipation, which progressed to obstipation so that he on one occasion failed to have a bowel movement for ten days. Anorexia, a gradual weight loss of some thirty five pounds, and weakness continued to increase apace. For some four weeks before admission his food had consisted entirely of fluids, and apparently as a result of this large fluid intake, polyuria and nocturia appeared. Furthermore he noticed increasing nervousness, sweating and palpitation. There was no gross hematuria or passage of urinary stones. At no time had he noted redness, swelling or local heat over the painful areas of the neck, knee and pelvic regions. There were no chills, fever, headache or vomiting. Because of the obvious grav-

ity of his illness, he was admitted to this hospital for further diagnosis and treatment.

The remaining family, marital and past histories were non-contributory.

Physical examination revealed an extremely emaciated but well-developed male who lay quietly in bed in some distress. His neck was held in a bivalved cast. On its removal nothing unusual was observed in the neck region save slight non-localized cervical vertebral stiffness and tenderness. The heart and lungs were normal. The blood pressure was 165 systolic, 110 diastolic. There was tenderness in the right flank and right costovertebral angle, without rigidity or palpable mass. The reflexes were depressed. There was no muscle fibrillation, but there was great generalized muscular atrophy. The remainder of the examination was negative.

The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 2,680,000, with 60 per cent hemoglobin, a hematocrit reading of 30 per cent, a color index of 1.12, a mean corpuscular volume of 115 cubic microns, a mean corpuscular hemoglobin of 34.2 micro-micrograms and a mean corpuscular hemoglobin concentration of 3.15 per cent. The white-cell count was 8450, with 64 per cent polymorphonuclears, 26 per cent lymphocytes, 3 per cent monocytes, 1 per cent basophils and 1 per cent eosinophils. The urine examination was negative, save that the Sulkowitch test for calcinuria was positive, there was no proteinuria. The blood Hinton test was negative. The serum calcium was 18.0 mg per 100 cc, the serum phosphorus 3.6 mg, the serum phosphatase 14.2 units and the serum protein 7.8 gm. The basal metabolic rate was + 16 per cent.

Roentgenograms of the bones of the pelvis, scapulas, mandible and visible portions of both femurs, as well as the sacrum were riddled with defects which varied in size from half to several centimeters in diameter. Similar changes were seen in several ribs, in the first and second lumbar vertebrae and in the fourth cervical vertebra. There was a compressed fracture of the last, as well as one of the second lumbar vertebra. In several places where the disease involved flat bones—in the pubic bones and in the ribs—there was expansion of the involved bones. The bones which were not involved showed fairly normal density. The lamina dura around the teeth, so far as could be seen in the skull films, was preserved. The wing of the ilium showed particularly marked involvement and was almost completely destroyed. Further x-ray studies, including intravenous py-

elography, were either negative or not dissimilar from those previously noted

The patient ran a slowly progressive, downhill course. On the tenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON I shall ask the x-ray consultant four specific questions. First, in regard to the pyelogram, is the dye concentrated sufficiently to suggest a fair renal function?

DR AUBREY O HAMPTON I should say that, if the patient were prepared for an intravenous pyelogram,—that is, if he were dehydrated before the dye was given,—there is something wrong with his kidneys which is probably functional. I cannot be sure of the type.

DR RICHARDSON Can you say anything about the size and shape of the kidneys?

DR HAMPTON I cannot see the kidney outlines due to the quality of the film, but the kidney pelvis on the right side is not dilated. The left kidney pelvis is not visible.

DR RICHARDSON Is there any calcium in the kidney or calcium stones elsewhere?

DR HAMPTON I have to take the report for that. This film was taken after the dye. Here on another film is a fairly dense kidney pelvis. Perhaps the kidney function was not so bad as I supposed on the first film. It seems to have been fairly normal, at least in one kidney.

DR RICHARDSON My last question is in regard to uninvolved bone. I should like again to have you say,—if it is so,—that the uninvolved bone is relatively normal.

DR HAMPTON I should say that the bone between the areas of destruction is entirely normal. The numerous punched-out areas of bone destruction produce an astonishing picture particularly in a man of his age. This film provoked a lot of "ah's" in the x-ray department when left on the illuminator. It shows a very extensive, purely destructive process in the bone of a young man. The disease did extend below the elbow at this point in the radius. The skull film is not here, but the lesions there were smaller but sharp and round, similar to this. These lesions in the pelvis are unusually large.

DR RICHARDSON I am no expert on bone disease or calcium metabolism. I shall probably make many mistakes which Dr Albright will immediately correct. I suspect this hook is baited with a choice morsel of parathyroid adenoma, but I am not biting for that. I do not see how it could be, for several reasons. In the first place, the phos-

phorus level is normal. Although one may get a normal or elevated phosphorus level in hyperparathyroidism, one has to presuppose then, I think, difficulty with renal function. I am going to speak of renal function later, but for the moment I shall assume that it was normal. In the second place, the phosphatase is distinctly elevated. It is my impression that, when hyperparathyroidism involves a large amount of bone, the phosphatase becomes greatly elevated. If it does not involve bone it will not be elevated at all. This process involves a tremendous amount of bone, and therefore one would expect with hyperparathyroidism an even higher phosphatase level. In the third place, it is difficult to see how a disease produced by overactivity of the parathyroid glands would produce localized lesions with normal bone elsewhere. Finally, the clinical course, which is rapidly downhill, suggests cancer rather than hyperparathyroidism, which in those cases I have seen has usually been a very much more chronic process.

Could it be secondary hyperparathyroidism? In certain cases of renal failure, there does occur, I believe, hyperplasia of the parathyroid glands. One explanation of this might be a retention of phosphorus because of damaged kidneys, with a resulting tendency to reduction of the blood calcium and an attempt on the part of the parathyroid glands to overcome this. That may be a silly explanation.

Is there any evidence of damaged renal function in this case? The patient shows clinical hypertension. The urine is reported as normal. If so, we are entitled to believe the specific gravity was above 1.020. No blood nonprotein nitrogen is reported—probably it is just as well. At least we have evidence that dye was excreted, although it may not have been excreted quite so well as normal. So on the whole it seems to me that we have very little evidence of renal failure. There may be a little. That may account for the phosphorus level as given here.

One other point—he had a macrocytic normochromic anemia. This is not uncommonly seen in uremia, but may also be seen in cancerous involvement of bone. In itself one cannot take that as evidence of renal failure. Therefore, I feel that it must be cancer. If so, what is it?

I shall rule out multiple myeloma on the basis of the patient's age. It is unusual to see myeloma in a patient this young. Otherwise it could be myeloma, it seems to me, there is no positive evidence of it, however. The serum protein was normal, and there was no Bence-Jones protein in the urine, though of course the latter does not have

to be present. No plasma cells were noted in the blood smear. Ordinary metastatic carcinoma from the thyroid gland, prostate or breast would seem very unlikely in this young man, therefore I shall rule that out. Also, the prostatic metastases to bone that I have seen have always shown a certain amount of osteoplastic activity, that is, increased density in the lesion. This lesion, as Dr Hampton pointed out, is almost purely osteolytic.

The next problem is lymphoma. Lymphoma not infrequently involves bone, but I have never heard of such extensive involvement as this—in my experience, two or three discrete lesions are the rule.

Finally, there is the question of renal carcinoma or hypernephroma. This seems to me the most likely diagnosis. There are one or two more points to be brought out about such a diagnosis. In the first place, could widespread malignant metastases to bone produce a blood calcium of 18 mg per 100 cc, a concentration which is very close to the lethal level? I do not know. I say it could because it apparently did. How could it? Obviously there was a terrific destruction of bone, and I suppose the calcium had to go somewhere. Another thing we notice is that he had constipation. We might even suspect—I do not know whether this can be proved—that calcium was not being excreted in the bowel in normal fashion and could not all get out through the kidney. I do not believe that I have to assume that this patient had hyperparathyroidism either primary or secondary to explain the high serum calcium. However, whatever the explanation of the serum calcium its high level seems to explain most of this patient's symptoms.

What positive evidence have we of renal carcinoma or hypernephroma? The only evidence is pain and tenderness in the right costovertebral angle and right flank. Possibly the obstruction may have had something to do with pressure in the region of the ascending colon. I think it is probably better to explain the constipation and obstruction on the basis of lack of food intake—starvation, in other words. The polyuria and polydipsia I assume are explained better as an attempt to excrete calcium than they are on any other basis. The nervousness, sweating, palpitation and muscular weakness could be due to a high blood-calcium level. Can high blood pressure be associated with it? I do not know. I might have looked up a number of these things, but I thought it would not be cricket to do that, so I have done the best I could with what I know. My diagnosis is renal carcinoma or hypernephroma.

DR. TRACY B. MALLORY: Are there any questions or comments?

DR. WILLIAM B. BREED: I think it is fair to say that everyone who saw him failed to make a diagnosis until the bone marrow was examined.

DR. BERNARD M. JACOBSON: The most important laboratory finding in ruling out multiple myeloma is the phosphatase. It does not help in the differential diagnosis, when elevated, between metastatic carcinoma and hyperparathyroidism. The last I heard about the case was that at quarter past nine this morning the pathologists were still working on the diagnosis. The sternal marrow cells, which I called something or other which I had never seen before, resembled lymphoblasts.

CLINICAL DIAGNOSIS

Lymphoblastic lymphoma.

DR. RICHARDSON'S DIAGNOSIS

Renal carcinoma or hypernephroma, with metastases to bone.

ANATOMICAL DIAGNOSES

Lymphoblastic lymphoma

Bronchopneumonia, slight.

Congenital anomaly—horseshoe kidney

PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Jacobson did a sternal puncture and the findings were later confirmed by a sternal biopsy. In the sternal puncture he found that erythropoiesis and myelopoiesis were markedly decreased. Nearly 90 per cent of the cells present were somewhat large, round cells, with very scanty bluish cytoplasm and a nucleus which was considered consistent with that of a lymphoblast. At the end of the autopsy I have nothing to add to that. I think we must consider this a lymphoblastic type of malignant lymphoma—lymphoblastic myeloma, if one wishes to call it that. The autopsy showed very extensive destruction of the bones, with numerous spontaneous fractures, including compressed fractures of two or three vertebrae. There was virtually no involvement outside of the skeletal system that one could recognize in gross. One kidney was horseshoe shaped, so it is not surprising that the outlines were difficult to make out. Its surface showed many poorly defined, mottled, grayish areas. On microscopic examination there were multiple foci of tumor cells scattered throughout the cortex. The spleen showed small numbers of scattered tumor cells but was not significantly enlarged. The liver showed very extensive hematopoiesis, evidently compensation for the great destruction of marrow.

CASE 26222

PRESENTATION OF CASE

A thirty-nine-year-old unmarried woman was admitted to the hospital complaining of pain and stiffness of the left knee

Approximately six months before admission the patient "spontaneously" developed stiffness of the left knee. This progressed and became painful. Pain was then present constantly and was aggravated by change of position after rest. There was only slight pain during actual weight bearing, but with walking and motion, however, the joint became swollen and required the use of an Ace bandage. She found that the application of ice packs relieved the pain, but that it was markedly aggravated by heat. She was acutely aware of weather change. Gradually the knee changed in shape. The patient lost 17 pounds in weight (from 112 to 95 pounds), was anorexic and stated that everything she ate produced "gas." Throughout the illness she continued to work as a boxmaker in a factory. There were no other symptoms, save easy fatigability and a constant feeling of lassitude. One month before admission she had had an attack of dysuria, frequency and slight gross hematuria, which lasted two weeks and then cleared spontaneously. Since that time she had remained asymptomatic.

At the age of eighteen she had had a pelvic operation resulting in an artificial menopause. The remaining family and past histories were non-contributory.

Physical examination, which revealed a pale, thin, undernourished woman, was essentially negative. She walked with a slight limp, and the left knee was held in flexion at 15° . There was a slight valgus deformity of the knee. The leg, just below the joint, was definitely enlarged, forming a mass that was more noticeable laterally. The veins over the enlargement were engorged. The mass was smooth in contour, firm, and definitely warmer than were the adjacent tissues. There appeared to be slight thickening of the joint capsule with no increase in joint fluid, and the area was tender to palpation both medially and anterolaterally. The head of the fibula was normal to palpation. Measurements of the legs were within normal limits, although 2.5 cm below the patella the left leg measured 30 cm in circumference, and the right 28.8 cm. The motion of the left knee was limited to flexion from 15° to 120° , while the right ranged from 0° to 140° .

The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 4,000,000 with a hemoglobin of 75 per cent, and a white-cell count of 6500 with 61 per cent polymorphonuclears. Examinations of the urine were negative. The serum calcium was 10.8 mg per 100 cc, the serum phosphorus 2.5 mg, the serum phosphatase 10.3 units and the serum protein 7.6 gm. The blood Hinton and Wassermann tests were positive.

Roentgenograms of the left knee showed that the proximal 6 cm of the left tibia close to the joint surface was markedly increased in density, the trabeculation being only incompletely visible. The increase in density was apparently produced by thickening of the cortical bone as well as by changes deeper in the bone. The bone surface was irregular in several places, without spicule formation. The appearance of the bone in these areas was more or less lacelike. No soft tissue mass was seen, but there was some slight swelling of the soft tissues along the medial aspect of the upper portion of the tibia. This extended upward to the level of the femoral condyle. Films of the skull and chest were negative. A gastrointestinal series was negative.

On the seventh hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR ROY E. MABREY: There are a few points that I should like to mention before we see the x-ray films. The duration of the disease—six months—is not of any help in making the diagnosis. The fact that the patient lost 17 pounds in weight may have been due to the pain she had in the leg, with consequent loss of sleep and appetite. She had easy fatigability and lassitude, which again might be non-specific responses to pain and loss of weight. She had dysuria and slight gross hematuria, both of which bring up an interesting possibility. The urine itself was negative, however, at the time she was admitted. No intravenous pyelogram was done, just a flat plate of the abdomen being taken. The operation that produced an artificial menopause probably does not have any bearing on the matter. The fact that she had no increase in joint fluid would tend to indicate that this was probably not an inflammatory condition, however, that does not always hold. The white count was 6500. The other tests were normal, except for the phosphatase, which was definitely elevated. She had a gastrointestinal series, demonstrating that some interest was taken in the anorexia and the belching of gas, and the results appear to rule out any primary lesion in the stomach.

May we see the x ray films?

DR. AUBREY O HAMPTON I cannot add anything to the note. The periosteal proliferation which produced the irregularity described is interesting I know the answer so I cannot go any farther

DR. MABREY The problem seems to be to differentiate inflammation and a neoplasm. Acute osteomyelitis we can rule out on the duration, the absence of fever and the white count. She might have had a low-grade form, a so-called Brodie's abscess, which could last for so long a period, but in view of the extent of the lesion I think she would have had something more in the way of elevated temperature and white count. A new entity, osteoid osteoma has been recently described. These lesions are quite small, however and do not reach the size of this one.

The next possibility is tuberculosis. That may occur around the joints. The skin of this patient was not white, as it is in tuberculosis the blood vessels were engorged, and the skin was warm to touch. So I feel that I can rule out tuberculosis.

She had positive Hinton and Wassermann tests so we must very seriously consider syphilis. The pain in syphilis of the bone is usually nocturnal although that is not always the case. With such a lesion we should expect a moth-eaten appearance, however, the lesion in this case is apparently one of a sclerosing type. The phosphatase in inflammatory lesions is usually normal, so that we have that evidence against its being syphilis.

When we come down to the neoplastic diseases there are a number we have to consider briefly. This episode of dysuria, with frequency and gross hematuria, brings up the question of whether she might have had osteitis fibrosa cystica. She could have had a parathyroid tumor with stones in the kidneys, but the laboratory tests rule it out. It is true the phosphatase was elevated but the lesion is single and we should expect it to be multiple. We can safely rule that out. Giant-cell tumor would not give this appearance by x ray, it is usually limited to the epiphyseal area. It is possible that it might have undergone malignant degeneration, however, and, if so, could have produced such a picture as this. This tumor does not extend up to the joint surface. You can see trabeculation of the bone up to the cartilage which would not be true of giant-cell tumor. With that much degeneration the tumor would extend up to the cartilage and not leave any bone there. Reticulum-cell sarcoma we should not have to consider seriously. Usually the patients are older than this. Such a lesion is very extensive, with

out causing marked constitutional reaction. We see patients with large lesions, and yet the general condition is very good. The question of metastatic carcinoma we have to consider again, and the urinary symptoms and the finding of blood in the urine at one time might suggest a hypernephroma that had metastasized to the bone. Of course such a tumor could metastasize to any area, however, no other foci were found. The stomach was investigated, presumably because cancer of the stomach sometimes metastasizes to bone. The thyroid gland and breasts were apparently normal in this patient. The serum phosphatase may be elevated in metastatic carcinoma, although in a single lesion it is usually not increased.

Another primary tumor we have to consider is Ewing's tumor. This case has none of the characteristics—no elevation of temperature, no increase in white count and no characteristic x ray film. As you know, with Ewing's tumor you see a lamination which gives the so-called onion peel appearance, and there is none of that here.

We come finally to osteogenic sarcoma. The duration of the story is consistent with that of an osteogenic sarcoma. The x ray picture is not typical because we usually consider that spicule formation is characteristic of this disease. There is involvement of both the cortex and the medulla of the bone. However, that is in favor of osteogenic sarcoma. The phosphatase is markedly increased, a finding that is consistent with osteogenic. It seems we come to three considerations: syphilis, metastatic carcinoma and osteogenic sarcoma. With the material at hand I favor osteogenic sarcoma.

DR. FULLER ALBRIGHT There are one or two interesting points that came up. In the first place, the crux of the matter is all in the phosphatase. With syphilis you only get bone formation and bone destruction in a small area, and not a high phosphatase. A high phosphatase would rule out a small lesion and would indicate osteogenic sarcoma or Paget's disease. Since it was not Paget's disease, I thought it was osteogenic sarcoma. I was sufficiently skeptical, however to insist that another phosphatase be done, it turned out to be 5 units.

CLINICAL DIAGNOSIS

Bone tumor?

DR. MABREY'S DIAGNOSIS

Osteogenic sarcoma

ANATOMICAL DIAGNOSIS

Bone syphilis

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY As Dr Albright has intimated, this did turn out to be syphilis. The clinical service refused to commit itself to any definite preoperative diagnosis, and the patient was operated on for biopsy. Frozen sections of the material removed at operation showed an inflammatory process, with no evidence of neoplasm, and the wound was closed after removing a few pieces of bone and of the surrounding soft tissues. In the final sections it was evident that we were dealing with a granulomatous type of infection. The predominant cell in the infiltrate was the plasma cell, and there were focal clusters of monocytes in tubercle-like groups, which are quite consistent with miliary gummas. There was absolutely no necrosis or destruction of bone, which would certainly have been present if the lesion had been tuberculous. After the histological finding and the positive serological tests I think there can be no

doubt that this was a syphilitic lesion. The patient is now under antisyphilitic treatment, and says that she feels very much improved.

DR HAMPTON In the x-ray seminar yesterday this case was shown, and I insisted that it was not osteogenic sarcoma because there was no soft tissue mass. If an osteogenic sarcoma involves that much bone you ought to have a big tumor. The periostitis on the lateral aspect of the tibia is that of a series of blunt hills, instead of ray formation. It is a very dense and well-organized periosteal reaction, indicating a chronic process.

DR WILLIAM B BREED I have been led to believe that the calcium and phosphatase determinations in this hospital are accurate and dependable. Does that hold with the phosphatase or should we be doubtful about them?

DR ALBRIGHT You might justifiably be doubtful about any chemical determination. The phosphatase level occasionally does jump up to 10 units for no reason. I do not know whether it is an inaccurate determination or whether something strange makes it do that.

SUBSCRIPTION PRICES: \$6.00 per year in advance, postage paid for the United States; Canada, \$7.00 per year; \$8.50 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Saturday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway Boston, Massachusetts.

A SYMPOSIUM ON MEDICAL CARE

THE School of Law of Duke University is engaged in a program to publish a series of group magazine articles designed to inform the public about matters of public interest in its quarterly periodical, *Law and Contemporary Problems*. Two numbers in this series have been published that are of interest to the medical profession. That of January, 1939, devoted to the administration of the new food, drug and cosmetic legislation, was commented on editorially in the August 31 issue of the *Journal*. The next publication, which appeared last October, is reviewed in this issue of the *Journal*. It includes fourteen articles by prominent lawyers, investigators and students of legislative procedures pertaining to public health, medical practices and the proposed insurance plans relat-

ing thereto which have been under consideration by state legislatures and Congress.

In these articles, especial emphasis is placed on two major trends in the field of medical care. The first consists of a discussion of the development of corporations and associations, sponsored either by medical organizations, by consumer groups or by governmental agencies, all organized to provide hospital service and medical care on a prepayment basis." The second deals with the principles underlying the administration of the plans for grants-in-aid of federal funds to extend state health plans, with particular consideration of the Wagner Bill, not so much however, in advocacy of the proposals but rather to clarify in the minds of the people the composition and functions of these several agencies now being devised for adoption or which may be created later. Although voluminous articles and discussions have been put before the public covering the attitude of the governmental agencies and the plans now in operation or under consideration by state, county and group medical organizations, there is, probably, a considerable proportion of the medical and lay public that has a vague or incomplete knowledge of the complicated problems involved, hence an evaluation of these articles by open-minded students of these subjects is helpful in developing practical solutions of the controversial propositions. Undoubtedly the School of Law of Duke University is engaged in a worthy effort to present evidential facts and the bearing of them on matters of importance before the citizens of this country.

At the present time the nation is being imperturbed by students of health problems to reconstruct its attitude and procedures relating to the prevention and treatment of disease. With this purpose in view, legislation is being devised in a program centered in the Wagner Bill or its successor, now before Congress, and it is pertinent that a non medical body representing a sister profession should present the results of its study of the situation and the proposed measures to be incorporated in this bill.

Most of the articles in the symposium have a

bearing on those sections of the bill and its associated provisions relating to health, and study of these papers will aid in the drafting of the indicated legislation. It is therefore appropriate that the medical profession and the public should unite in the expression of appreciation of the work of the authors of these papers

THE RISK OF BIOPSY

ONE of the deterrents to early and accurate diagnosis of malignant tumors has been the fear, more or less unwarranted, that biopsy might lead to dissemination of the neoplastic cells. On the basis of clinical experience, however, the advantages of accurate knowledge of the nature of a tumor far outweigh theoretical dangers of metastasis. In addition, some data based on observations on animal tumors are available. A curious commentary on our occasionally illogical thought is provided by those who unhesitatingly curette a uterine neoplasm and yet balk at biopsy of a breast tumor.

From any aspect it is better when possible to excise a tumor nodule intact and thus avoid the potential spreading of tumor cells. When this is not possible, various means of obtaining tissue have been proposed, such as aspiration biopsy. Aspiration biopsy is not so favorable for diagnosis as methods giving more adequate tissue, but is relatively simple.

The dangers of incisional biopsy have probably been exaggerated. A recent important contribution on this subject has been made by Paterson and Nuttall,* who followed a group of patients with epidermoid carcinomas of the skin and mucous membranes of the mouth which were treated by radiation. Early lesions, without clinical evidence of involvement of the lymph nodes, had biopsy specimens removed by sharp ring forceps, no electrocoagulation was used, and the portions of tissue removed were large. All cases were treated essentially alike and seen in the regular

follow-up clinic of the hospital, 202 cases were initially included in the study but certain ones were discarded because they did not entirely meet the criteria. Finally 99 cases with biopsy and 67 cases without biopsy were studied from the standpoint of metastasis, 19 per cent of the biopsied cases showed metastasis, and 20 per cent of the non-biopsied cases.

This careful piece of work demonstrates that in carcinoma of the skin and mucous membranes biopsy does not increase the likelihood of metastasis. It is probable that a similar study of carcinomas of the breast or of the rectum would have a similar result.

MEDICAL EPONYM

BUCK'S EXTENSION

The extension apparatus which bears Gurdon Buck's (1807-1877) name was first described by him before the New York Academy of Medicine at a meeting held on March 20, 1861. A report of the paper was given by Dr. George F. Shrady in the *Bulletin of the New York Academy of Medicine* (1:181-188, 1861).

A roller bandage is commenced at the toes in the usual way, and continued to the ankles, where it is temporarily arrested. A band of adhesive plaster two and a half to three inches broad, and long enough to allow the middle of it to form a loop below the sole of the foot, and the ends to extend above the condyles of the femur, is then applied on either side, in immediate contact with the limb, from the ankle upwards. Over this the bandage is continued as high up as the plaster. A thin block of wood of the width of the plaster, and long enough to prevent pressure over the ankle, is inserted into the loop, and serves for the attachment of the extending cord, which is fastened to an elastic rubber band (such as is used for door springs), that passes round the block.

The limb is now prepared to be put under extension. A strip of inch board three inches wide is fastened upright to the foot of the bedstead, and perforated at the height of four or five inches above the level of the mattress. Through this hole the extending cord is to be passed, and on the further side of the strap a screw pulley should be inserted at the proper level over which the cord, with the weight attached, is to play. Coaptation splints should be secured by elastic bands. Counterextension must be maintained by the usual perineum band lengthened out in the direction of the long axis of the body, and fastened to the head of the bedstead.

RAYMOND S. TITUS, M.D. *Secretary*
330 Dartmouth Street
Boston

PYELITIS OF PREGNANCY

Mrs. C. C., a thirty-eight year-old primipara, four months pregnant, was admitted to the hospital on September 6, 1935, with chills, fever, malaise, nausea and vomiting. She gave a history of having had these symptoms for two months.

The family history was negative. The patient's past history was essentially negative. Catamenia began at thirteen, were regular with a twenty-eight-day cycle, and lasted five days. The last period was April 20, making the expected date of delivery January 27, 1936.

Physical examination showed a well-developed and well-nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The uterus was enlarged to a size consistent with the period of amenorrhea, and a uterine fibroid was evident on palpation. The urinary sediment showed large numbers of white blood cells in clumps, there were no red cells and no casts. A urine culture showed *Bacillus coli*. Blood examination showed the hemoglobin to be 80 per cent, the red-cell count 3,870,000, and the white-cell count 8600. A blood culture taken on September 7 showed *Staphylococcus albus*.

On September 9 the hemoglobin was 80 per cent, the red-cell count 3,800,000, and the white cell count 10,500. She was transfused with 300 cc. of citrated blood.

The temperature rose steadily until it reached a peak of 103.6°F on the fifth day then gradually dropped until it reached normal on the tenth day.

On September 15 the patient was cystoscoped. The infected right renal pelvis was irrigated with boric acid solution, the catheter being left in place for twenty-four hours. The patient was discharged on September 29, asymptomatic.

The patient was carried to term with some difficulty, her general health being poor. She was admitted to the hospital at term on January 27, 1936. At that time her urine still showed many white cells but there were no definite kidney complaints. The delivery was uneventful, as was the postpartum course.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Comment This case illustrates the modern treatment of pyelitis with kidney lavage and with catheter drainage for twenty-four hours, cultures of the blood and urine having been taken. Transfusions in small amounts are often very beneficial to patients who become run-down and anemic from pyelitis, and the small transfusion in this case was done for its tonic effect rather than because of severe anemia as at the time the hemoglobin was 80 per cent and the red-cell count almost 4,000,000. No subsequent attack of pyelitis occurred before delivery.

DEATHS

HARDING — GEORGE F. HARDING, M.D., of Brookline, died May 16. He was in his seventy-ninth year.

Born in Dorchester, he attended Harvard University and received his degree from Harvard Medical School in 1889. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, two sisters and a brother survive him.

KENNELLY — JULIA G. KENNELLY, M.D., of Cambridge, died February 9. She was in her seventy-second year.

Dr. Kennelly received her degree from the Woman's Medical College of Pennsylvania in 1900. She was a former member of the Massachusetts Medical Society, and had retired from active practice.

SHATTUCK — ALBERT M. SHATTUCK, M.D. of Worcester, died May 26. He was in his seventy-first year.

Born in Groton, he received his degree from the Dartmouth Medical School in 1895. He was on the staff of the Worcester City Hospital and the Memorial Hospital, Worcester for many years. Dr. Shattuck was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow and a son survive him.

STILES — FRED M. STILES, M.D., of Waltham, died recently. He was in his seventy-seventh year.

Born in Westbrook, Maine, he received his degree from Bowdoin Medical School in 1890 and did postgraduate work at Harvard Medical School.

Dr. Stiles was a member of the Massachusetts Medical Society and the American Medical Association.

His daughter survives him.

SWEENEY — JOHN G. SWEENEY, M.D., of Hingham, died May 16. He was in his forty-sixth year.

He received his degree from Tufts College Medical School in 1916. Dr. Sweeney was former medical examiner for the Plymouth District and a former member of the Massachusetts Medical Society.

MISCELLANY

NEW CHARITY TO CORRECT
SPEECH DEFECTS

A Massachusetts charter has just been granted the Institute for Speech Correction Incorporated, organized without capital stock to give the most up-to-date instruction in overcoming stammering, lipping and other speech defects exactly at cost. This new corporation has taken

over the Boston Stammerers' Institute, which was the oldest school of its kind in America

Arrangements have been made with Emerson College whereby adequately supervised advanced students in speech pathology will instruct without charge any pupil at the institute who, on recommendation of his family physician, cannot pay for his lessons

The following public spirited educators, psychiatrists and business men have been elected trustees and are giving their services without compensation Harry S. Ross, president of Emerson College, Frederick C. Packard, Jr., associate professor of public speaking, Harvard University, Dr. Edgar C. Yerbury, director of the Division of Mental Hygiene, Massachusetts Department of Mental Health, Joel W. Eastman, attorney, John M. Taylor, banker, Seth T. Gano, bank director and trustee, Dr. Douglas A. Thom, professor of psychiatry, Tufts College Medical School, and Payson Smith, LL.D., lecturer at Harvard University Graduate School of Education.

Samuel D. Robbins, permanent secretary of the American Speech Correction Association and professor of psychology at Emerson College, has been elected managing trustee. Mr. Robbins was for twenty-five years director of the Boston Stammerers' Institute, which was founded in 1867

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MARCH, 1940

| DISEASES | MARCH 1940 | MARCH 1939 | FIVE YEAR AVERAGE* |
|--------------------------|---------------|---------------|-----------------------|
| Anterior poliomyelitis | 1 | 0 | 0 |
| Chickenpox | 1471 | 1181 | 1376 |
| Diphtheria | 9 | 14 | 19 |
| Dog bite | 732 | 754 | 738 |
| Dysentery bacillary | 36 | 24 | 6 |
| German measles | 56 | 105 | 1248 |
| Gonorrhea | 308 | 384 | 461 |
| Lobar pneumonia | 609 | 900 | 723 |
| Measles | 1487 | 4290 | 3034 |
| Meningococcus meningitis | 3 | 5 | 19 |
| Mumps | 866 | 1015 | 1260 |
| Paratyphoid B fever | 11 | 1 | 2 |
| Scarlet fever | 607 | 895 | 1233 |
| Syphilis | 501 | 416 | 551 |
| Tuberculosis pulmonary | 242 | 315 | 296 |
| Tuberculosis other forms | 20 | 28 | 38 |
| Typhoid fever | 3 | 4 | 5 |
| Undulant fever | 5 | 3 | 3 |
| Whooping cough | 644 | 970 | 946 |

*Based on figures for preceding five years

RARE DISEASES

Anterior poliomyelitis was reported from Boston, 1, total, 1

Diphtheria was reported from Abington, 1, Boston, 3, Chelsea, 1, Fall River, 1, Monson, 1, Waltham, 1, Wrentham, 1, total, 9

Dysentery, bacillary, was reported from Amherst, 2, Attleboro, 1, Belchertown, 24, Beverly, 1, Boston, 1, Malden, 1, Marblehead, 1, Northampton, 1, Norwood, 1, Sterling, 3, total, 36

Infectious encephalitis was reported from Melrose, 1, Webster, 1, total, 2

Leprosy was reported from Medford, 1, total, 1

Meningococcus meningitis was reported from Chelsea, 1, Hadley, 1, Wilmington, 1, total, 3

Paratyphoid B fever was reported from Arlington, 1, Boston, 1, Brookline, 2, Marblehead, 1, Milton, 1, Revere, 2, Salem, 1, Wakefield, 1, Worcester, 1, total, 11

Pfeiffer bacillus meningitis was reported from Dracut, 1, Mills, 1, total, 2

Septic sore throat was reported from Boston, 10, Box-

ford, 3, Cambridge, 6, Fall River, 3, Lexington, 1, Malden, 1, Medford, 3, New Bedford, 1, Sturbridge, 2, Water town, 1, Webster, 1, Whitman, 1, total, 33

Tetanus was reported from Boston, 1, total, 1

Trachoma was reported from Boston, 2, total, 2

Trichinosis was reported from Boston, 1, Lynn, 3, total, 4

Typhoid fever was reported from Lynn, 1, North Andover, 1, Somerville, 1, total, 3

Undulant fever was reported from Boston, 1, Greenfield, 1, Springfield, 1, Wayland, 1, Williamstown, 1, total, 5

The reported incidences of chickenpox and undulant fever were slightly above the five-year averages.

Paratyphoid B fever had its highest March incidence since 1934

Bacillary dysentery, primarily of the Sonne type, continues to be prevalent, although at a slightly lower level than that of last month

Diphtheria, German measles, measles, mumps and lobar pneumonia were reported well within the five year averages

The reported incidences of anterior poliomyelitis, dog bite, gonorrhea, syphilis and whooping cough were at expected levels

There was nothing remarkable in the reported incidences of tuberculosis, typhoid fever and scarlet fever

NOTES

The appointment of Dr. Walter L. Mendenhall, professor of pharmacology at Boston University School of Medicine, to the advisory board of the *United States Pharmacopoeia* was recently announced.

The appointment of Dr. William T. Green as director of the After-Care Clinic of the Harvard Infantile Paralysis Commission was recently announced at Harvard University. He was appointed assistant professor of orthopedic surgery this spring at Harvard Medical School, and since 1934 has been a member of the staff of Harvard Medical School and of the Children's Hospital, Boston.

The members of the commission are Dr. John E. Gordon, chairman, and Drs. Kenneth D. Blackfan, C. Sidney Burwell, Cecil K. Drinker, Frank R. Ober, Alton S. Pope, George B. Wislocki and Hans Zinsser.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on February 13, with Dr. Elliott C. Cutler presiding.

The first case presented was that of a forty-one year-old man who entered the hospital complaining of progressive weakness and pains shooting down the backs of both legs. One year prior to admission he had successfully passed an insurance examination. One month before entry he had noted a slight upper-respiratory infection, and this was followed by a typical attack of lobar pneumonia with hemoptysis and a temperature of 103°F, successfully treated with sulfapyridine. He never seemed to recover and began noting weakness and shooting leg pains. Physical examination was negative except for tenderness of the left hip and both gastrocnemii and pain on flexion of the left hip. Routine laboratory studies were normal. A flat plate of the abdomen revealed destructive lesions in the

bony pelvis and lumbar spine and subsequent roentgenograms showed a lesion diagnosed as primary carcinoma of the lung. Pain was essentially unrelieved by x-ray therapy.

In discussing the case Dr. Merrill C. Sosman reminded the audience of the frequency with which pulmonary carcinoma has its first manifestations in its metastases and is ushered in by one or more attacks of pneumonia.

The surgical case was that of a thirty-nine year-old man who was brought to the hospital in a semicomatose state after allegedly being struck and injured by an automobile. The patient entered with multiple contusions and abrasions. The temperature was 101 F., the pulse 140 and the respirations 20. He was found by x-ray study to have a compound, comminuted fracture of the left lower leg which was debrided under spinal anesthesia. Gas-bacillus antitoxin was administered. Lumbar puncture revealed a bloody fluid, but the patient was not subjected to x-ray studies of the skull. His course in the hospital was one of gradual mental clearing and general improvement. Dr. Cutler congratulated the house staff on refraining from taking x-ray films of the skull, for he considered the condition of the brain more important than that of its casing. He also reminded the audience that accidents in the home are the only ones more frequent than those caused by the ubiquitous automobile.

The speaker of the evening was Dr. Alan R. Moritz, professor of legal medicine at the Harvard Medical School, whose subject was "The Application of Medical Science to the Administration of Justice." He pointed out that despite the existence in European universities of departments of legal medicine for fifty to one hundred years, the recent establishment of such a unit at Harvard Medical School was the first of its kind on this continent. Dr. Moritz criticized our coroner system, inherited from England, because of the uncertain political tenure of the coroner who is not even required to have professional qualifications. A non-political medical examiner's system is much better.

To emphasize the importance of a qualified professional physician as medical examiner Dr. Moritz referred to typical incidents where competent judgment was necessary. In regard to homicide, the time of death may be important, even if only approximate; this can be estimated in numerous ways. The circumstances of death may be ascertained by the configuration of fracture lines, by the path of a bullet or by the gastric contents.

An interesting study in New York City has shown that 40 per cent of adult pedestrians killed by automobiles were under the influence of alcohol. This was considered important collateral information in placing blame in such cases. The same investigation revealed that almost 50 per cent of fatal assaults occurred in persons whose alcoholic content in the brain was at such a level that it was likely to predispose to quarreling. Frequently knowledge of this character constituted valuable evidence in assessing the degree of guilt of an accused person.

Dr. Moritz stressed the importance of investigating cases of sudden death even though there is no evidence of unnatural causation. Many such cases are found at autopsy to have resulted from unsuspected physical or chemical injuries. Similarly the finding of numerous cases of poisoning recently in Philadelphia and Cincinnati has confirmed the feeling that an untold number of such unsuspected unnatural deaths probably occur in this country and pass unnoticed in those communities not supplied with a competent medical-examiner system.

Another phase of death wherein such a system clarifies matters is that which concerns those who die of natural

causes but with external signs of violence. Dr. Moritz alluded to the fact that there are many people walking about, driving cars and frequenting places where unexpected collapse is almost sure to result in violent injury. The latter has often been the death-certificate diagnosis when there was either no autopsy or only a superficial one, whereas the true cause of death might well have been a coronary thrombosis. The speaker cited as an illustration the unfortunate husband who was sentenced to prison for homicide because he slapped his wife's face shortly before she was stricken with a cerebral embolus arising from a diseased heart. Actually about five of every one hundred deaths thought clinically to be due to violence, are found at autopsy to have resulted from natural causes.

Dr. Moritz also referred to the great loss to vital statistics each year because of incomplete investigation of cases of sudden or unexpected death. Many deaths from diseases such as tuberculosis, syphilis, poliomyelitis, meningitis, pneumonia, and so forth escape recognition.

Methods at the disposal of the scientific investigator of crime were discussed briefly by the speaker. Among the important chemical studies are the recognition of alcohol in the tissues and the diverse methods of running down "story-book" clues. The latter were held to be of practical importance in many cases. Microscopy also plays a role in this regard but Dr. Moritz suggested that it is probably more important to know where to get expert assistance than it is to attempt to maintain a complete consulting staff in each laboratory.

In regard to the problem of medical testimony in court the speaker warned of the dangers of expecting a judge or jury to be able to choose competently between the testimony of partisan rivals in psychiatric cases. He advocated instead the appointment by the court of a nonpartisan medical expert for all such problems. Dr. Moritz also criticized a too strict adherence to the doctrine of protection against self-incrimination. By improperly employing this defense, a lawyer may refuse to allow routine physical examination or urinalysis, as well as more elaborate tests on clothing, hair and so forth of his client.

NOTICES

ANNOUNCEMENT

THOMAS J. CAVANAUGH, M.D., announces the opening of an office at 270 Commonwealth Avenue Boston

REMOVAL

H. S. QUEEN, M.D., announces the removal of his office to Hotel Brandon Hall, 1501 Beacon Street, Brookline.

NEW ENGLAND HEALTH EDUCATION ASSOCIATION

The annual conference of the New England Health Education Association will be held Friday and Saturday June 7 and 8 at the Massachusetts Institute of Technology in Cambridge.

The conference will open Friday afternoon with inspection of the exhibits and a social hour followed by the annual business meeting at 5:30 p.m. The guest speaker at the dinner (6:30 p.m.) will be Helen S. Mitchell, Ph.D., research professor of nutrition at the Massachusetts State College in Amherst. Her subject will be, "Food Facts and Fallacies."

On Saturday morning Samuel Prescott, Ph.D., will give the address of welcome. Henry Otto, Ph.D., consultant

in education of the W K Kellogg Foundation, Battle Creek, Michigan, will speak on "Health Education and Its Relation to Public Health and Medical Care." Other speakers will be Miss Helen Almy, director of social service at the Massachusetts Eye and Ear Infirmary, who will speak on "A Medical-Social Approach to a National Health Program," and Dr Allan M. Butler, of Boston, who will speak on "The Need for Conservatism in the Provision of Budgeted Medical Services"

The conference will close with a luncheon Miss Mabel C Bragg, Boston University, will be the speaker Miss Mabel M Brown, president of the association, will preside.

HARVARD MEDICAL ALUMNI ASSOCIATION

The annual meeting and dinner of the Harvard Medical Alumni Association will take place on Wednesday, June 12, at 7 15 p.m. at the Harvard Club of New York during the annual session of the American Medical Association. The speakers will be President James B Conant and Drs C Sidney Burwell, Lincoln Davis and Cornelius P Rhoads

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held in the classroom of the nurses' residence on Thursday evening, June 6, at 7 15 p.m. The program will consist of case presentations of cardiac disease, maternity deaths and diarrhea with the autopsy results

1940 GRADUATE FORTNIGHT

The 1940 Graduate Fortnight of the New York Academy of Medicine will be held from October 14 to 25. The purpose of this meeting is to make a complete study and authoritative presentation of a subject of outstanding importance in the practice of medicine and surgery. The current topic is "Infections."

There will be a carefully integrated program, which will include morning panel discussions, afternoon clinics and clinical demonstrations at many of the hospitals of New York City, evening addresses and appropriate exhibits. The evening sessions of the Academy will be addressed by recognized authorities in their special fields, drawn from leading medical centers of the United States. The comprehensive exhibit will include books and roentgenograms, pathologic and research material, and clinical and laboratory diagnostic and therapeutic methods. It is also planned to provide demonstrations of exhibits.

The following subjects will be included: experimental basis of chemotherapy in the treatment of bacterial infections, clinical bacterial chemotherapy, results obtained and dangers encountered, a general consideration of bacterial infections, recent advances in knowledge of streptococcal infections, infections of the mouth, pharynx and upper respiratory tract, infections of the middle ear and nasal sinuses, infections of the teeth and surrounding structures, influenza, pneumococcal infections, bacterial meningitis, infections of the urinary tract, gonococcal infections in the male, gonococcal infections in the female, osteomyelitis and pyogenic infections of the joints, wound infections, puerperal infections, treatment of infections by methods other than chemotherapy, virus infections, acute poliomyelitis, brucellosis—undulant fever, rickettsial diseases, lymphogranuloma venereum, epidemic encephalitis, other forms of encephalitis and choriomeningitis, and exanthematous diseases.

litis, other forms of encephalitis and choriomeningitis, and exanthematous diseases

The Academy provides this program for the fundamental purpose of medical education, consequently all members of the medical profession are eligible for registration. A complete program and registration blank may be secured by addressing Dr Mahlon Ashford, New York Academy of Medicine, 2 East 103d Street, New York City

CHILDREN'S MEMORIAL HOSPITAL, MONTREAL

The Annual Postgraduate Course which has been given for the past three years at the Children's Memorial Hospital, Montreal, will not be held this year. It is not the intention of the hospital to discontinue the course, but rather to postpone it, due to the war and to an extensive building program. As soon as conditions permit, the course will be resumed with improved facilities.

BOOK REVIEWS

Medical Care Vol. VI No. 4 *Law and Contemporary Problems* 182 pp. Durham, North Carolina: Duke University School of Law, 1939. 75 cents.

This volume, the Autumn, 1939 issue of *Law and Contemporary Problems* contains fourteen articles, contributed by men all holding scientific or professional degrees. Each of these contributions is worthy of elaborate analysis but space is not available for more than a discursive review with the hope that sufficient interest will be aroused for their more detailed study.

The first article, by I. S. Falk, member of the Interdepartmental Technical Committee on Medical Care, gives the historical background of the awakened and progressive interest in the socioeconomic proposals set forth in the subsequent chapters. His contribution is an informative and logical disquisition concerning the facts and experiences which have influenced earlier workers in the fields of public health and economics pertaining to medicine.

The second, by Martin W. Brown, general secretary Bureau of Co-operative Medicine, carries the theme of the first through the history of some experimental organizations. He describes the economic and varying problems of medical care which have arisen because of the advances in the application of scientific knowledge, the development of medical institutions and the growth of specialties leading to the operation of eight groups engaged in furnishing medical care, thereby showing the differences in the fundamentals that prevail in the experiments which have

been made to determine the success of such organizations.

Joseph Laufer, editor-in-chief of the *Duke Bar Association Journal* in the third article discusses that type of medical care which is classified as contract practice and which includes the intermediate offices of a third party, individual or organization who or which contracts with physicians individually or collectively for service to a group of patients. He includes a history of group and contract practice and of the operation of these organizations, which, in certain instances, ran counter to the ethical principles adopted by the American Medical Association.

The fourth article under the caption "Enabling Legislation for Non-Profit Hospital Service Plans" is by C. Rufus Rorem, the director of the Commission on Hospital Service of the American Hospital Association. After showing that hospitalization is one of the unpredictable and expensive forms of health service which together with other incidental expenses constitutes an economic hazard that can be logically avoided by resort to insurance, the author explains the attitude of the states in dealing with the problems raised by insurance methods to spread the costs of medical care. This has required the study of state laws which vary widely as shown in decisions by state insurance departments where the ruling has been that hospital-service insurance necessitates special enabling acts. That this plan for enabling acts is not a simple solution of the problem is shown by the many essential details of administration.

Maunce J. Norby, research director of the Council on Hospital Service Plans of the American Hospital Association continues the discussion of hospital-service plans including their contract provisions and administrative procedures, in the fifth article. He describes hospital service as a form of protection which means collective co-operation in the equalization of losses resulting from the uncertainty of health but states that it is not health insurance since it provides for only one form of health service through a corporation. He then proceeds to define the different forms of contracts and the subscriber's relations thereto. In this scheme, group enrollment is essential for apparent reasons. This article is a continuation and amplification of the facts and theories and the details of operation set forth in the preceding chapter and should be studied with the other.

The sixth article, presented by William J. Burns, executive secretary of the Michigan State Medical Society deals with the medical-service problems of Michigan culminating in the passage of the first group-medical-care enabling act on the statute books of a large industrial state, which was the result of the combined efforts of the state government, the state medical society and the state department of insurance. Payments for the benefits provided in the act include private corporations, association groups, individuals and the governmental agencies (in behalf of indigents). Each contract is with the subscriber patient so that no third party comes between the patient and physicians. This act has served in many particulars as a model for others.

Another illustration of a non-profit medical-service corporation is presented by Hartley F. Peart, president of the Bar Association of San Francisco and Howard Hassard, member of the California Bar in the seventh chapter. The managerial functions in this plan are carried by a board of trustees and the service is conducted by California physicians who are paid by the so-called unit system which distributes the accumulated pool funds among the participating physicians. Full beneficiary memberships are applicable to those whose family incomes do not exceed \$3000 a year but families in the higher brackets are eligible for benefits on payment of additional fees to the doctor.

The eighth article is under the title of "The Medical-Care Program for Farm-Security-Administration Borrowers," by R. C. Williams, who began his career as a practitioner of medicine and after three years entered public-health service and now is chief medical officer of the Farm Security Administration, and deals with 100,000 low-income farm families that are borrowers from this administration. The service became necessary because of the economic distress of 3,000,000 farm families in more than twenty states. The illness problem of this large group, which is both a cause and a result of poverty, involved the necessity of devising plans which would ensure medical care at rates bearing relation to the financial situation and the co-operation of physicians in the adjustment of fees. State medical associations co-operated in the plans adopted in conformity with principles promulgated by the American Medical Association. All the administrative details are set forth in this article and cover the various forms of service.

The ninth chapter deals with the "Anti-Trust Prosecutions against the American Medical Association," contributed by Benjamin D. Raub, Jr., the current-decisions editor of the *Duke Bar Association Journal*. This article gives a description of the organization of the Group Health Association, Incorporated, of Washington, District of Columbia, a non profit co-operative organization for the purpose of furnishing medical care and hospitalization to its members and their dependents on a risk-sharing prepayment basis. It is a voluntary association with membership originally limited to employees of the Home Owner's Loan Corporation, with the further explanation that the only connection between the federal government and the Group Health Association was a grant of \$40,000 by the Home Owners Loan Corporation, made because of the opinion that the Group Health Association would reduce the loss of employees' services through illness. Congress discussed the propriety of this grant but took no action. Later the Group Health Association voted to include as eligible for membership all civilian employees of the executive branch of the government and voted to assess themselves to create a fund for repayment of the grant of the Home Owners' Loan Corporation.

The Medical Society of the District of Columbia initiated a policy of opposition to the Group Health Association. The legality of the association was questioned in suits brought by the insurance commissioner of the District of Columbia on the ground that it was engaged in the insurance business and by the United States district attorney on the ground that it was a corporation engaged in the practice of medicine. The court held that neither of these allegations was correct. Then followed suits against the American Medical Association, the Medical Society of the District of Columbia, the Harris County Medical Society of Texas and certain individuals for alleged violation of Section 3 of the Sherman Act, which declares it a misdemeanor to "engage in any combination or conspiracy in restraint of trade in the District of Columbia."

A summary of the indictment is to the effect that the defendants conspired to restrain the Group Health Association in its business of arranging for the provision of medical care and hospitalization to its members and their dependents, to restrain its members in obtaining by co-operative efforts adequate medical care for themselves and their dependents from doctors engaged in group-medical practice, to restrain doctors serving on its medical staff, to restrain other doctors in the District of Columbia in the pursuit of their callings, and to restrain the Washington hospitals in the operation of their business

The defendants demurred to the indictment. Judge Proctor of the District Court of the District of Columbia decided in favor of the defendants, sustaining the demurrer. The government petitioned the Supreme Court of the United States for a writ of certiorari which, if granted, would permit appeal to the Supreme Court, this was denied. The rest of the article is devoted to a review of the legal questions raised by the demurrer, as submitted by both sides, and is a voluminous digest of the purposes and meaning of the language of the Sherman Act.

This is an important precedent which may have repercussions in future cases, because it seems to be established that medical societies, organized legally and with rules relating to membership or behavior of members that are not found to be illegal, may find that other organizations engaged in furnishing medical care may not meet the approval of the local medical society.

The tenth chapter is devoted to the "Background of the Wagner National Health Bill," by Harold Maslow, formerly staff member of the Committee on Research in Medical Economics. This bill is based on earlier experiences, studies, conferences and enactments relating to or brought about by socioeconomic conditions.

The Act passed in 1918 provided federal grants to state venereal disease programs. Other bills for grants-in-aid followed, but many health problems received little legislative encouragement until the passing, in 1921, of the Sheppard-Towner Bill, which provided grants to states for infant and maternal hygiene. In 1934 President Roosevelt appointed a committee to draft a social security bill which provided for federal grants for public health and infant and maternal hygiene, these were amplified in 1939 under the social security provisions of the Wagner Bill.

After the passage of the Social Security Act, the President appointed an Interdepartmental Committee to coordinate health and welfare activities. This committee in turn appointed the Technical Committee on Medical Care to continue studies of the 1934 committee. These committees submitted two reports in 1938,—"The Need for a National Health Program" and "A National Health Program,"—which were submitted to Congress and designed to interest the people in the extension of medical services according to a ten-year program, with the result that, in 1938, representatives of the professions, labor, farmers and civic bodies were invited and came to the National Health Conference.

Since that time there has been a tendency to endorse the propaganda of unmet health needs and focus public discussion on plans for meeting such deficiencies. The reports of these committees were presented to Congress with the result that the Wagner Bill was introduced. Extensive hearings on the bill were conducted with farmers, labor interests and some physicians in favor and the American Medical Association in opposition. In August 1939, the subcommittee reported agreement with the general purposes and objectives of the bill, with recommendation for further study.

The provisions of the Wagner Bill, which is, in substance, a series of amendments to the Social Security Act with some new features, are fully discussed. In this account there is abundant opportunity for the student to speculate on the questions which naturally arise when individuals engage in propaganda concerning complicated economic or sociological problems in which health plays a prominent part. Sympathy for human suffering and political expediency may perhaps point in one direction with the possibility of

another by a mind swayed by emotion rather than logic. It is certainly true that when questions of relief from human suffering are to be considered, those people who are trained to deal with ill health are best qualified to solve many of these problems and should be recognized rather than those who see political advantage in large expenditure of public funds; hence it is reasonable to expect that in dealing with health matters every opportunity for co-operation by the medical profession should be cordially encouraged. The Wagner Bill has been a source of controversy which might have been avoided if in its earlier stages, cordial relations with the medical profession had been established.

The eleventh chapter deals with "Public Medical Services also under Title VIII of the National Health Bill," the author being David F. Cavers, professor of law Duke University who shows that the implications in the bill indicate that under its provisions there is the possibility of the enactment of compulsory health insurance in addition to uncontroversial projects. He goes on to show that since the depression the burdens imposed by illness and indigency have been too heavy for the support of tax payers, hospitals, physicians and very many charitable agencies. In order to meet these conditions, the Emergency Relief Administration was devised, and in 1934 twenty nine states were receiving assistance from this organization but even so the situation was not satisfactory, according to a report of the Committee on Medical Care of the American Public Welfare Association in 1938.

The twelfth chapter presents "Legislative Proposals for Compulsory Health Insurance," by Louis S. Reed, chief of the Medical Economics Section Health Studies Division Bureau of Research and Statistics, Social Security Board. In connection with studies of the desirability of legislative action, he submits the drafts of three state bills in addition to a model bill composed by the American Association for Social Security which was drawn in co-operation with leading authorities. The first had been drawn up in California by the Governor's Committee on Health Insurance the second had been introduced in the New York Assembly the third had been considered in the Wisconsin Assembly in 1937 a few changes having been made by Mr. Andrew Biemiller. Not one had been enacted up to the writing of this chapter. These four bills are designed to provide adequate medical care and spread the burden of illness costs and all exclude from compulsory coverage the self-employed and two exclude farm and domestic service workers. All, except the California bill, limit compulsory coverage to manual workers and non manual employees earning less than \$3000 a year.

The fundamental principles here set forth are very much like those in old-age insurance, and questions arise as to the limits of health insurance to incomes, in so far as the medical service in the low-income groups may not equal that provided for the well-to-do and the complications incident to administration of these laws.

The thirteenth chapter by I. S. Falk, L. S. Reed and B. S. Sanders, the last being chief of the District of Columbia Bar covers the "Formulation of Disability Insurance." They show that because of the effects of the depression the United States is following the trend in other nations toward social insurance which in wider scope, will lessen the insecurity due to loss of earnings through unemployment, as already provided in certain provisions by the federal government and forty seven states. In the Wagner Bill, under Title XIV, a proposal is submitted for a federal-state system of temporary disability insurance, and this, with proposed amendments in H. R. 6635 seems

to be a pattern for the development of an amplified form of social insurance. The need for this seems indicated by the amount of dependency traceable to disabling illness and by the wage losses due to disabling illness as shown by opinions founded on fact finding studies indicating that thirty five per cent to fifty per cent of poverty asking for relief is due to sickness. Statistics in this article are submitted in confirmation of these facts.

As the argument proceeds from explanation of the underlying causes and varieties of disabilities, all the complicating factors are discussed in extenso and the varieties of relief indicated are defined in the conclusion reached that disability and invalidity insurance will necessitate a sharing of the costs by employers and employees and further that large expenditures by federal state and local governments are warranted because the security now provided is inadequate.

The last chapter by Clarence Heer professor of economics at the University of North Carolina is devoted to a study of the formula for grants-in-aid and of the Wagner Bill which is officially entitled the National Health Act of 1939. This is "primarily a grant-in-aid measure" with detailed specifications covering conditions under which the several states may if so desired receive funds from the federal government to assist them in specified health services under their own devised and administered plans. It provides an appropriation of \$98,000,000 of federal money during the first year of operation of which \$89,000,000 will be paid to the states as grants-in-aid, with the understanding that such grants will depend on the states raising matching funds. If state co-operation is forthcoming "it is estimated that some ten years hence, when the program reaches its maximum federal grants for various public services, for medical care to the needy and for the construction and maintenance of hospitals but excluding grants for state sickness-insurance claims, will reach a total of \$425,000,000 per annum." With matching state appropriations, the sum will be \$850,000,000 and will represent a net addition to the \$571,000,000 of federal state and local funds which according to estimates, are now being spent on public health services and hospital care in the United States.

Anyone interested in the published facts and conclusions which have appeared in the last decade pertaining to the sociological problems of health and to the laws designed to broaden the scope of measure dealing with them will find in these papers a résumé of facts and opinions which have a bearing on the changing attitude of the public toward medicine. There is, however a rift to be bridged before the ethical principles of the profession will be generally interpreted and adopted by the public this will be accomplished only when there shall have been brought about a more general appreciation of the devotion of the profession to human needs. Now that the legal fraternity has shown its interest in the accomplishments of medicine there should follow an enthusiastic endorsement of the aims and purposes of organized medicine.

Sclerosing Therapy The injection treatment of hernia hydrocele varicose veins and hemorrhoids Edited by Frank C. Yeomans. 337 pp. Baltimore. Williams & Wilkins Co. 1939 \$6.00.

In this book, treatment by the injection of sclerosing fluids into hernias, hydroceles, varicose veins and hemorrhoids is considered. The last two topics, presented by Shelley and Yeomans respectively are clear well illustrated and conservative expositions which can be read with profit by those interested.

As Hoch points out in the second article, the surgical

treatment of hydrocele is accompanied by a rather high incidence of wound complications. Injection treatment, which is well described, should therefore have much to offer, but one is disappointed to find no statistical analysis of the results or complications of the method.

The same criticism can be made, to a considerable extent, of the first and longest article in the book. In it, Bratrud carefully reviews the subject of the injection treatment of hernia from the point of view of ten years' experience as director of the clinic for ambulant treatment of hernia of the University of Minnesota Medical School. Indications, contraindications and technics are well described and illustrated, but in the chapter on results one finds only very scanty data on the duration of cure. The most careful, and discouraging, study of end results that has thus far appeared, that of Burdick and Coley from the Hospital for the Ruptured and Crippled of New York City, is dismissed in a sentence.

It seems to the reviewer that the author of this section, in common with all protagonists of the injection method of treating hernia, bases his work on the false assumption that scar tissue will not stretch. If such were the case infected abdominal wounds healing by secondary intention should never herniate, but unfortunately they do with considerable frequency. However, for those few individuals who refuse operation or for whom operation is contraindicated, the method is worthy of trial.

For the surgeon who is called on to employ sclerosing therapy the book can be highly recommended.

The Physiological Basis of Medical Practice. A University of Toronto text in applied physiology. Charles H. Best and Norman B. Taylor. Second edition. 1872 pp. Baltimore: Williams & Wilkins Co., 1939. \$10.00.

The first edition of this book was issued in 1937 and at once became the standard and most popular book of its day, linking together the preclinical subject of physiology and that of medical practice. A large book, full of material, it has become a bible of the junior clinician, for it bridges his medical school work with actual contact with patients in the clinic or hospital. Accurately written, extensively documented and widely supplied with charts and diagrams, it is not surprising that this book has been reprinted four times before a second edition was called for two years after the first was issued.

In this new edition, the material has been carefully revised, and a new section on the special senses added. In order to save space, which is an important consideration in a book of its size, the titles of papers have been omitted from references, unless necessary for the identification of the paper. There is an extensive bibliography by chapters at the end of the book, listing not only the important papers on the subject but also monographs and reviews. In addition, the book is thoroughly indexed. As a reference book, this volume is outstanding.

Health in Handcuffs. John A. Kingsbury. 210 pp. New York: Modern Age Books, Inc., 1939. 75c.

This book, written by the former executive officer of the Milbank Fund, is published for the purpose of showing that health administration and the resources of scientific medicine are not operating to capacity because of several inhibiting factors. After an appreciative tribute to the medical profession and other agencies included in dealing with the problems of illness and the economic complications incident thereto, the author explains the complexities involved in the adjustment of the resources of this nation to the prevailing sociologic conditions and expresses his belief that health insurance in one form or another will

play an important part in dealing with them. Endorsement of the principle underlying group practice and adequate hospitalization of a larger proportion of the population are among other propositions advanced.

The major trend of the belief of Mr. Kingsbury, however, is in the advisability of the passage of the health program as set forth in the Wagner Act and to this end a large proportion of his arguments is directed. This has brought him into conflict with the attitude of the American Medical Association, which he assails in the spirit of a crusader.

The book is well written and contains much information covering the propositions of federal bureaus and departments with respect to the health program defined in the bill before Congress.

Bergey's Manual of Determinative Bacteriology. A key for the identification of organisms of the class schizomycetes. David H. Bergey, Robert S. Breed, E. G. D. Murray and A. Parker Hitchens. Fifth edition. 1032 pp. Baltimore: Williams & Wilkins Co., 1939. \$10.00.

The practicing bacteriologist cannot but feel that he owes a debt of gratitude to those of his colleagues who have been willing to keep this now well-established manual up to date. To review it properly would require a detailed study which the present reviewer has not been able to give. In the past he has found occasional errors in this book or, let us say, points in which his opinion differed from that of the original author. But these were never important and did not diminish the great importance of the manual as a reference book for all bacteriological laboratories.

The task of the present authors has been rendered particularly difficult by the changes in bacterial classification which have resulted from the newer knowledge of dissocation. They are aware of this, however, and the reviewer agrees with them that none of this work has necessitated fundamental changes in a systematic classification of this kind. The bacteriologist who, like the reviewer, is engaged in the study of purely pathogenic bacteria is quite incompetent to judge the book as a whole. But in those sections with which he is familiar he finds this new edition as valuable as he has found preceding ones. The nomenclature is a bit confusing to the "old hand," who has difficulty in recognizing some of his old friends under new names. And he is apt to wonder why such first cousins—almost twins—as the gonococcus and meningococcus which, unless the source is known, are not easy to tell apart, are separated in different families seventeen pages apart. But these and similar examples are all points in which legitimate differences of opinion are possible and do not detract from the great value of this book which performs a difficult and necessary service.

Lane Medical Lectures. Viruses and Virus Diseases. Thomas M. Rivers. 133 pp. Stanford University, California: Stanford University Press, 1939. \$2.50.

Dr. Rivers, director of the Hospital of the Rockefeller Institute for Medical Research, has had published in book form the Lane Medical Lectures, given by him in 1938. The subject is highly technical but of great interest to physicians who are keeping up with progress in bacteriology. Dr. Rivers discusses lymphocytic choriomeningitis, the pathology of virus diseases, immunologic and serologic phenomena of virus diseases, and their treatment and prevention. The work summarizes the latest advances in this field of medicine and, as such, is an invaluable addition to medical literature.

BLOOD-PHOSPHORUS STUDIES IN RHEUMATIC FEVER*

NATHAN EPSTEIN M.D.† AND FRANCIS C. McDONALD M.D.‡

BOSTON

SEVERAL years ago it was noted that many children hospitalized with acute rheumatic fever had been attending our outpatient clinic for months before the appearance of symptoms definitely attributable to their disease. During this period the presenting signs and symptoms were chronic fatigue and failure to gain weight. The occurrence of chronic undernutrition prior to the onset of the symptoms of rheumatic fever stimulated closer analysis of this factor. In the group of patients studied, signs of malnutrition were common. This was attributed to diets inadequate in proteins, minerals and vitamins and relatively rich in carbohydrates, maintained over long periods. One of the essential elements which was deficient was phosphorus. The known relatively high requirement of phosphorus for optimal growth and its role in muscle metabolism prompted an investigation of its content in the blood of a small group of patients.

For the determination of phosphorus the method of Tisdall¹ was used in the earlier part of the study, however, 70 per cent of all the analyses were made with the colorimetric method of Fiske and Subbarow.² Analyses were performed on the bloods of 38 patients. The samples were taken before breakfast, and the examinations were started within half an hour of the drawing of the blood. Analyses were made of the inorganic phosphorus and the total phosphorus of the serum, and of the phosphorus in the alcohol-and-ether-soluble and acid-soluble fractions of whole blood. The latter fraction contains inorganic phosphorus, phosphoric esters and undetermined compounds. Finally, the total phosphorus content of the whole blood was determined.

The following is a brief outline of the procedure used. The details may be found elsewhere.^{3, 4}

Half a given sample of blood was placed in a paraffined centrifuge tube and promptly centrifuged. The serum thus obtained was divided into four samples. Trichloroacetic acid was added to one sample, which was then filtered. The protein-free filtrate was analyzed for inorganic phosphorus by adding ammonium molybdate and amino-naphthol sulfonic acid, which produces a color change to blue. After suitable dilution this was compared colorimetrically with a known standard. The other three samples of serum were digested with sulfuric acid. The last stage of the digestion was carried out with superoxal (this contains 0.0005 per cent phosphorus). The clear digest after suitable dilution and addition of ammonium molybdate and amino-naphthol sulfonic acid was compared colorimetrically with standard solutions. This analysis gave the total amount of phosphorus in the blood serum.

The other half of the freshly drawn venous blood was placed in a glass bottle containing a small amount of potassium oxalate. This oxalated whole blood was divided into five samples. Three of these were digested with sulfuric acid for the determination of the phosphorus content of whole blood. The fourth sample was treated with trichloroacetic acid, filtered and analyzed for the acid-soluble fraction. The fifth sample was used for determination of the phosphorus of the alcohol-and-ether-soluble fraction by adding a 3:1 mixture of alcohol and ether bringing to a boil, cooling and filtering. Portions of the filtrate were digested and prepared for the analyses.

The values recorded in Table 1 and Figure 1 represent the averages of three determinations on all blood fractions with the exception of inorganic phosphorus, wherein two determinations were made. The total of the acid-soluble and alcohol-and-ether-soluble fractions approximated the total blood phosphorus and served to check the analyses. The results were compared graphically with average values derived from controls from this clinic and with similar values derived from obtaining the average of a larger control series that included the cases of Stearns and Warweg.^{5, 6} These workers made a complete study of the phosphorus of the blood in a group of 124 children.

*From the Boston Floating Hospital, the Children's Department of the Boston Dispensary and the Pediatric Department of Tufts College Medical School, Boston.

†This study was made possible by a grant from the Charlton Research Fund of Tufts College Medical School.

‡Formerly Charlton Research Fellow, Tufts College Medical School.

§Assistant professor of pediatrics, Tufts College Medical School; physician in Boston Dispensary.

The 33 patients from this clinic included 18 who showed clinical and laboratory evidence of rheumatic fever (The blood sedimentation rate was considered to be the most reliable laboratory means of judging activity of the disease) The 15 controls consisted of patients with sinusitis, pyelonephritis, skin lesions or arrested tuberculosis Five

patients from the North Reading State Sanatorium with active tuberculosis were also studied (Table 2) With these exceptions the controls were in the convalescent stages of their respective illnesses

In whole blood as well as in the acid fraction the highest values obtained in the rheumatic series were invariably lower than the minimum control values, including those of the North Reading group The depletion of phosphorus was most marked in the organic fraction The average reduction of phosphorus in the whole blood of the patients with rheumatic fever as compared with the controls was 15 per cent There was a corresponding reduction of the available acid-soluble fraction as well as of the alcohol-and-ether-soluble fraction There was a smaller reduction of about 10 per cent in the available serum phosphorus

DISCUSSION

It is not impossible that the variations from normal in the rheumatic fever group are to be expected as the result of the disease itself, and have little to do with the nutritional state prior to the development of clinical and laboratory signs of rheumatic fever However, an analysis of the

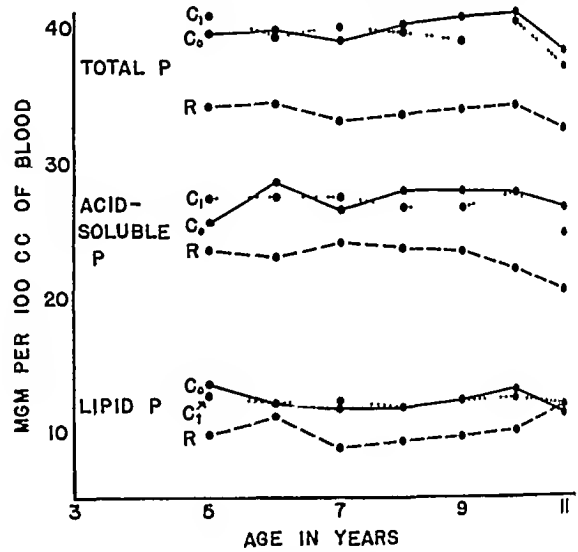

FIGURE 1 *Phosphorus Partition in Whole Blood*
C₀—average of controls (20 cases)
C₁—weighted average of controls, including Stearns and Warweg's patients (49 cases)
R—average of patients with rheumatic fever (18 cases)

problem of 65 patients in this clinic who had rheumatic fever and had clinical records antedating the proved diagnosis, as summarized in Figures 2 and 3, is strongly suggestive that the factors which tend to lower the hosts' resistance in this disease are important

In this group comparatively large families (with

an average of seven members) lived on incomes averaging about \$15 a week Consistent with the low incomes, more than 70 per cent of the patients had been inadequately nourished for several years The nutritional histories showed that the diets were relatively rich in carbohydrates and

starches and relatively poor in proteins, minerals and vitamins. Many of these children were ailing several months before they developed clinical signs and laboratory evidence that resulted in a diag-

weight over periods of six months or longer. Anorexia was a commonly associated complaint.

Numerous studies⁴⁻¹⁵ indicate that rheumatic fever has a much higher incidence among the

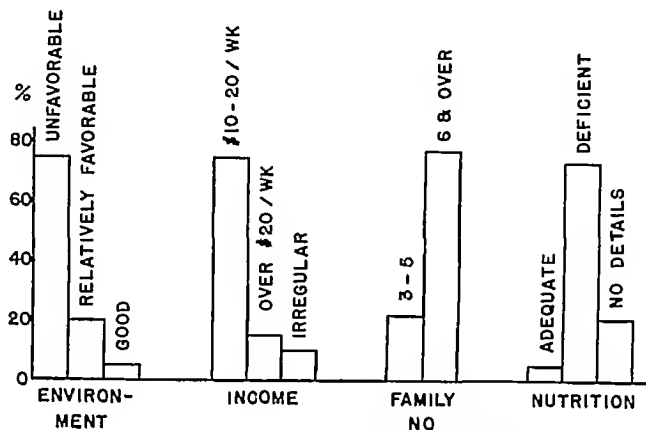

FIGURE 2 Contributory Factors in Early Cases of Rheumatic Fever

nosis of rheumatic fever. Each patient included in our group had been followed for a varying length

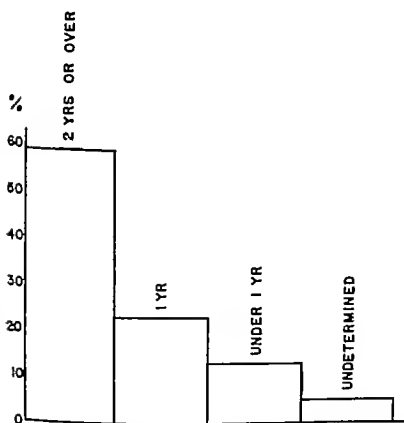

FIGURE 3. Duration of Symptoms before Development of Clinical Signs and Laboratory Evidence Which Resulted in a Diagnosis of Rheumatic Fever

of time (three months to five years) before the diagnosis of rheumatic fever was entertained.

The most tangible evidence of undernutrition in the patients studied was a cessation of gain in

economically handicapped than among the economically independent. Those who emphasize the spread in recent years of rheumatic fever in localities said to have formerly been relatively free from the disease should take into consideration the gradual development of living conditions in these areas similar to those found in areas where the disease has been prevalent. The diets under such conditions tend gradually to become deficient in proteins, minerals and vitamins and relatively rich in the carbohydrates and starches found in less expensive foods.

Chronic fatigue was also manifested in our patients, first by lassitude and inactivity, secondly by nervous instability and wasteful overactivity. Restless, fitful sleep disturbed by night terrors was not unusual. Respiratory infections accelerated the decline in health of the patients, together with the gradual appearance of recurrent episodes of muscle joint and visceral pain, both diffuse and localized.

This prevalence of chronic fatigue, followed later by many symptoms involving muscular tissue, raises the question of possible disturbances of metabolism of muscular tissue. Although our knowledge of the chemical reactions which occur during muscular contraction and recovery is far from complete, phosphorus compounds are considered essential for normal activity. Fiske and Subbarow¹⁶ followed by Eggleston and Eggleston¹⁷ isolated phosphocreatine from muscle in 1927.

Chemical analyses have shown that probably 80 per cent of the creatine in resting muscle occurs as phosphocreatine. The theory has been advanced that the cleavage of phosphocreatine is the primary change that supplies the energy for normal muscular contraction. Phosphate esters including the nucleotide, adenylypyrophosphate, apparently play intermediary roles in muscular contraction and recovery.

Presumably anemia in itself should reduce the total phosphorus of whole blood. Control patients were chosen who had a reduction in erythrocytes and hemoglobin corresponding to that found in the patients who had rheumatic fever. The average hemoglobin value in both groups was about 75 per cent. The average erythrocyte count of the 20 controls was 4,500,000, and with few exceptions the count in the individual case was well over 4,000,000. The lowest control values were in a child who had lost considerable blood in the stools. His blood phosphorus values were low normal. Hematocrit readings were taken in 18 patients, including 12 with rheumatic fever. The average value for the latter was 40 per cent, as compared with 42 per cent for the controls.

SUMMARY

The phosphorus content of the whole blood has been found to be relatively low in children with rheumatic fever, as compared with that of patients

who are in a better state of nutrition, and with that of patients convalescing from acute and other chronic illnesses.

END RESULTS OF USE OF LARGE DOSES OF AMPHETAMINE SULFATE OVER PROLONGED PERIODS*

WILFRED BLOOMBERG, M.D.†

BOSTON

AMPHETAMINE (Benzedrine) sulfate was introduced into therapy in December, 1935.¹ Since our report of its use in narcolepsy, many studies have been carried out, and numerous reports have appeared in the literature which deal with the physiology, clinical uses and toxicology of this interesting drug. The effects of amphetamine on blood pressure, mood, intelligence and gastrointestinal functions have been exhaustively studied. The great majority of reports, however, deal with the effect of single doses, or of small doses over a comparatively short period of time. Ulrich² in October, 1937, reported follow-up studies on some of his narcoleptic patients

after months of treatment. However, the effect on the bodily physiology of extremely large doses over comparatively long periods of time has not so far been reported. It seemed worth while, therefore, to present the results of studies of 3 patients with narcolepsy who have been taking at least 70 mg of amphetamine sulfate every day, for two years and eight months in 2 cases, and for one year and eight months in 1. Two of the patients were cases in our original series, and the third started treatment some time after the original group.

METHOD

The three patients all suffered from narcolepsy and cataplexy. In 2 cases these symptoms developed after an attack of encephalitis lethargica, and

*From the Department of Neurology Harvard Medical School and the Neurological Unit Boston City Hospital

†Instructor in neurology Harvard Medical School, assistant visiting neurologist Boston City Hospital

in 1 of these the narcolepsy was accompanied by postencephalitic parkinsonism, in the third case the narcolepsy was of the so-called idiopathic type. Two patients were women aged twenty-seven and twenty-three, and 1 was a man aged sixty-two. In 2 cases fairly complete laboratory studies of the pre-treatment period were available in the third these were unfortunately not at hand.

In the follow-up studies, each of the 3 patients

informed of smears. A careful history was taken, and general physical and neurological examinations were made. In taking the history, special emphasis was placed on eliciting evidence of abnormal cutaneous manifestations and of gastrointestinal symptoms.

Not every one of the tests was carried out on each patient, but a sufficient number of laboratory investigations was made in each case to uncover any abnormality of function of any system

was admitted to the hospital for a period of observation and study of at least three days. In order to determine whether there were any toxic effects on the kidneys, urine examinations, Mosenthal tests and phenolsulfonephthalein excretion tests were carried out, and the blood nonprotein nitrogen was determined. For the effect on the liver, icteric index and Takata-Ara tests were done. The effect on the cardiovascular system was studied by four hourly blood-pressure readings during the entire stay in the hospital, and by seven foot heart x-ray plates in 2 cases. In 1 case in which a pre-treatment electrocardiogram had been taken, this was repeated.

The endocrine system was studied by determination of the basal metabolic rate and the blood sugar, and by charting the pulse rate, as well as by inquiring into a history of change in weight. The blood was studied by counts and the exam-

COMMENT

Reference to Table 1 will show that in spite of the massive doses of amphetamine, continued over a comparatively long period, no significant abnormality was found in any of the tests. The temperature, pulse and respiratory rate were normal throughout. There was no increase in the basal metabolic rate and no rise in blood pressure. There was no evidence of damage to the kidneys or liver. The blood and certain of its constituents showed no deviation from the normal.

General physical and neurological examinations were entirely negative in all cases. None of the patients had suffered skin or gastrointestinal disturbances. They were all keeping awake on amphetamine sulfate, and were able to carry on their work. Cataplexy was almost entirely relieved in each. None of them had had to increase

the dose of amphetamine after the adjustment period of the first few weeks, and one (Case 1) had actually found that she could lower it. None of them felt any craving for the drug or was unwilling to stop taking it during the study period. The usual comment was, "Now that I'm in bed and have nothing to do and don't mind sleeping, I don't mind not taking the pills."

My recent experience with amphetamine sulfate has included the treatment of a great number of alcoholic patients. These patients do not, of course, take such large doses, but some of them take as much as 50 mg per day, and in no case in my series has there been any significant difficulty attributable to the drug for more than a day or so. No patient in my experience has had to give up his medication because of untoward side effects. Nor have I observed any evidence, in either the narcoleptic or the alcoholic group, of addiction, habit formation or increase in tolerance after the first two or three weeks of treatment. Incidentally, though other writers have warned against the use of amphetamine sulfate outside the hospital, all these patients have been ambulatory, and no difficulties have been en-

countered because of this fact. One alcoholic patient did, indeed, because of his state of intoxication at the first interview, misunderstand his instructions. He thought the tablets were a sedative, and so took more and more as he became more excited. He had finally consumed 150 mg in about fourteen hours, but other than a sleepless night and a jumpy irritability, lasting about thirty-six hours, he suffered no ill effects.

SUMMARY AND CONCLUSIONS

Three patients with narcolepsy who had been taking 70 mg or more of amphetamine sulfate daily for two years and eight months in 2 cases, and for one year and eight months in 1 case, were studied.

No significant deviation from normal, as a result of this large dosage, was found in any case by any laboratory or clinical study.

No evidence of addiction or habit formation was found.

PREVENTION AND MANAGEMENT OF PAIN FOLLOWING CHOLECYSTECTOMY*

JOHN M. MCGOWAN, M.D.,† AND FRANCIS F. HENDERSON, M.D.‡

BOSTON

A GREAT deal has been said and written in recent years concerning unsatisfactory results following surgical removal of the gall bladder. After being exposed to a procedure of such magnitude the patient expects to enjoy good health and freedom from symptoms. Unfortunately, in many cases the pain and discomfort return, and are as severe after operation as they were before it.

We have divided our cases into two groups: those in which the pain was produced from the beginning, by disturbances outside the biliary system, and those in which the symptoms were caused primarily by disease in the biliary tract and in which cholecystectomy was a necessary procedure. In the first group, obviously no relief can result from removal of the gall bladder, even though it might incidentally have been diseased. It is with the second group of cases that this paper is concerned.

In order to prevent recurrence of biliary colic

after operation, it is necessary for the surgeon to have a complete understanding of the physiologic disturbance involved. McGowan, Butsch and Walters¹ early in 1936 demonstrated that biliary pain could be produced by increased pressure within the bile ducts. This pressure is often due to obstruction in the common duct, which may be the result of an unsuspected stone, swelling in the head of the pancreas, a stricture of the common duct or spasm of the muscle at the lower end of the common duct. It was found that morphine produced this spasm, and in a number of cases the resulting back pressure in the bile ducts produced biliary colic. The drug when given in large doses relieved the pain by acting on the cortical centers, but it augmented and prolonged the spasm. In this way it exposed the bile ducts to periods of distention lasting from eight to twelve hours.

When the bile ducts are dilated, high tensions are developed within them as a result of increased pressure. These tensions are poorly withstood by the thin-walled ducts and pain results. Morphine relieves the pain, but appears to shorten the inter-

val between subsequent attacks. Inhalation of amyl nitrite or the sublingual administration of glyceryl trinitrate (nitroglycerin) relaxes the spasm, reduces the pressure and relieves the pain (Fig 1) Nitroglycerin, in doses of one or two

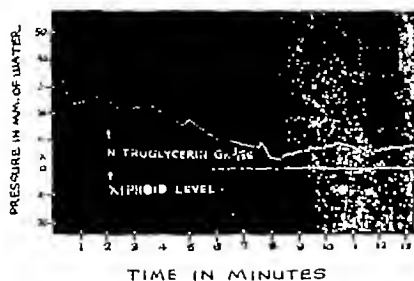

FIGURE 1

Pressure-tracing of the common duct showing only a slight increase in the resting pressure. Reduction of the pressure by means of glyceryl trinitrate indicates the presence of duodenal spasm. Roentgenograms of this case are illustrated in Figure 3

tablets, each containing 1/250 gr., has been found to be of consistent potency. In a recent publication² it was shown that the sphincter mechanism of the common duct is the muscle of the duodenal wall. Since a physiologic sphincter functioning independently of the duodenal wall has never been demonstrated, it seems proper to use the term "duodenal spasm" where the term "spasm of the sphincter of Oddi" is generally employed. The physiological principles just outlined should be kept in the foreground of the surgeon's mind if he is to prevent biliary complications after cholecystectomy. The first step in this direction is the proper use of T-tube drainage of the common duct.

T-TUBE DRAINAGE

T-tube drainage decompresses the ducts of the biliary tree. This allows the ducts in many cases to return to normal size and the inflammation in them to subside. The ducts are then able to withstand higher pressures without producing pain. An indwelling T tube in the common duct allows future detailed study of the patency of the papilla of Vater by a series of pressure studies. Also, it permits roentgenographic studies for the detection of missed common-duct stones.

At the time of operation the common duct may be opened in most cases before removal of the gall bladder. The clamped cystic duct may be used as a retractor to steady the common duct. Indications for opening the duct are a history of

jaundice, the presence of a palpable stone in the duct, a markedly dilated duct and inflammation in the head of the pancreas. Lahey³ estimated that 40 per cent of all cholecystectomies should be accompanied by exploration of the common bile and hepatic ducts. In each case a T tube should be left in the common duct for drainage.

During exploration of the common duct the patency of the papilla of Vater should be determined by passing graduated, soft woven catheters down through the common duct into the duodenum. Zollinger⁴ has stated that No. 10 Fr. is the size of the average lumen of the papilla of Vater in the human subject. Overdilation of the papilla of Vater may lead to scar formation, and to narrowing of the lumen to less than its original size.

The T tube is best brought to the surface in the center of the wound. It should be placed so that there is an excess of tube between the common duct and the abdominal wall. This allows a certain play on the tube by the movements of the abdominal wall in respiration. If this precaution is not taken the gradual pull on the tube will kink the common duct. The tube should be fastened to the skin with a silk suture. Care must be taken not to constrict the tube.

In the aftercare of these patients it is very important to have a proper method for collecting the bile. Nothing must be attached to the tube which might pull on it. A suitable apparatus consists of an 8-ounce flat medicine bottle with a baby's nipple attached. The bottle is fastened to the binder by means of adhesive tape. The end of the T tube should be pushed through a hole in the nipple. This hole must be sufficiently large to allow the escape of air. If not, pressure within will stop drainage. After the patient becomes ambulatory, a small hot water bottle with a metal tube inserted through the stopper makes a convenient bag for collecting bile.

Two weeks after operation tests are carried out in order to determine the probable duration of T-tube drainage. These consist in determinations of the resting intrabiliary pressure, and of the perfusion pain level and roentgenographic studies of the biliary tract.

RESTING INTRABILIARY PRESSURE

The resting intrabiliary pressure is measured by a special apparatus, described elsewhere.¹ This apparatus is built around an ordinary Y shaped glass tube. The stem of the Y is attached by means of a rubber tube to a bottle of intravenous saline solution. To each limb of the Y tube is attached a rubber tube one of which is to be connected to the T tube in the patient, the other to

an upright spinal manometer. The tubing is filled with saline solution from the reservoir bottle before it is connected to the patient. The zero level of the manometer should be placed at the level of the xiphoid process of the sternum. The resting fluid level in the manometer is ordinarily at about this point. If the resting fluid level is considerably above the base line, say 30 to 100 mm, one should suspect some partial obstruction in the lower end of the common duct. This may be due

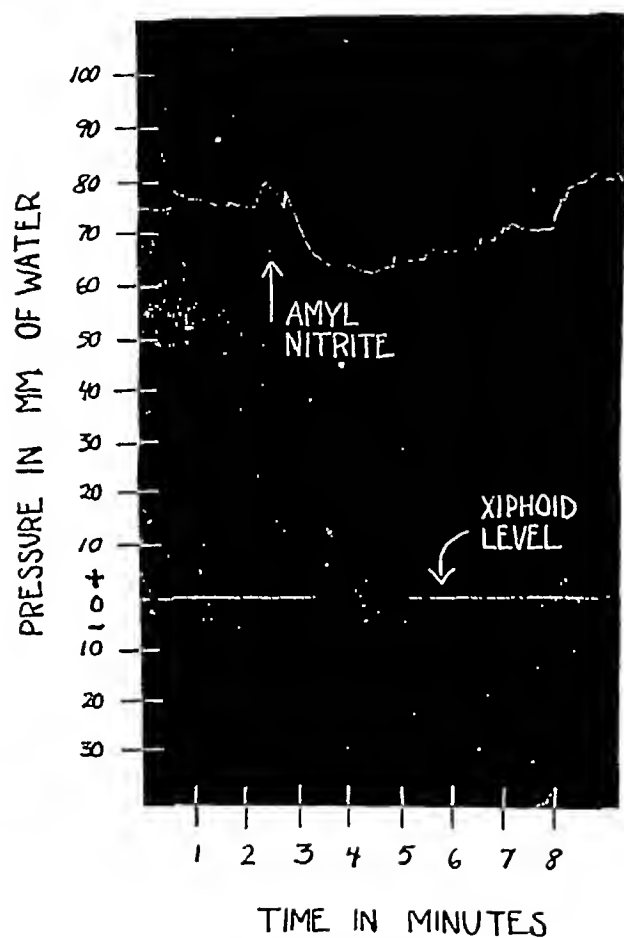

FIGURE 2

Pressure tracing of the common duct illustrating a moderate increase in the resting pressure above the normal. Amyl nitrite produced only partial reduction in the pressure. This shows that the pressure is due partially to spasm but chiefly to a more permanent cause. Roentgenograms of this case are illustrated in Figure 4.

to pressure from inflammation in the head of the pancreas, spasm of the musculature of the duodenal wall, a missed stone in the common duct or edema of the duodenal mucosa at the ampulla of Vater.

Five deep inhalations of amyl nitrite will aid in determining the nature of the obstruction. If this medication reduces the pressure to normal, the obstruction is due entirely to spasm. If it fails

to reduce it, the obstruction is of a more permanent nature. If it reduces it incompletely, obstruction is due partially to spasm and partially to some more permanent cause (Fig. 2).

PERFUSION PAIN LEVEL

Perfusion of the common duct is done in order to determine the amount of pressure that it will withstand without producing discomfort. The lowest pressure level in the common duct at which the patient complains of pain is referred to as the "pain level." Some patients experience pain when the biliary tree is exposed to relatively low perfusion pressures, at times not over 70 mm of water. In other cases pressures of 500 mm or more may be tolerated without discomfort. There are two reasons for this difference. In the first place, if the bile ducts are dilated, high tension is developed by relatively low pressures. Secondly, if the ducts are inflamed from the presence of infection, they withstand pressure rather badly. The bile passages should be able to resist pressures of 300 mm of water without producing pain. This is usually the maximum secretion pressure of the liver. If pressures below 300 mm of water produce pain or discomfort, the patient may expect to have recurrence of distress after removal of the T tube. On the other hand, if the bile ducts are decompressed for a sufficiently long time by T-tube drainage, dilatation and infection will improve and the bile ducts can resist relatively high pressure. Under these circumstances, if the patient subsequently has duodenal spasm for a few hours the resulting back pressure in the bile ducts will not produce pain.

To determine the pain level the pressure apparatus is connected to the patient as described. The reservoir bottle is lowered until its fluid level is the same as that of the zero level of the manometer. The clamp is taken off the rubber tube from the reservoir bottle, which is slowly elevated until the patient experiences discomfort. The fluid level in the manometer is then read. This reading is the pain level. The tube from the reservoir bottle is reclamped. The fluid in the manometer then falls in two to five minutes to a level equal to the resting intrabiliary pressure. The perfusion pain level should be over 300 mm of water, the resting intrabiliary pressure should be less than 30 mm of water.

ROENTGENOGRAPHIC STUDIES OF THE BILIARY TRACT

For roentgenographic studies the patient is placed flat on his back on the x-ray table and all the preparations to take the pictures are made,

10 cc. of Diodrast* in a syringe is injected slowly into the T tube. A roentgenogram is taken immediately. The tube is clamped, and a second roentgenogram is taken ten minutes later. Study of the films will show whether any obstruction to the flow of bile into the duodenum exists. Obstruction is indicated by extreme dilatation of the main ducts and small branches of the biliary tree,

Stricture of the mucous membrane of the ampulla of Vater is indicated in the lower end of the common duct by the presence of a blunt rounded termination (below 6 in Fig 4B).

In these cases the opaque medium frequently outlines the proximal portion of the pancreatic duct. When the medium is injected, epigastric pain is often experienced. This pain is undoubt-

FIGURE 3

A. This film shows the common duct under resting conditions. The numbering in this illustration and in Figure 4 is as follows: 1 common duct 2, point at which the bile enters the duodenal lumen 3 contrast medium in the duodenum 4 hepatic ducts and the finer radicles in the biliary tree 5 pancreatic duct 6 point at which the common duct begins to penetrate the musculature of the duodenal wall 7 T-tube 8 cystic duct 9 Sawyer tube passed through the nose into the duodenum. Definite narrowing of the common duct can be seen at 6. This is due to spasm. The portion of the duct between 6 and 2 is that part which tunnels the duodenal wall the intramural portion.

B. This film of the same case was taken ten minutes after the subcutaneous injection of $\frac{1}{4}$ gr. of morphine. The spasm at 6 has greatly increased producing almost complete obstruction. The common duct is much more distended as a result of back pressure.

and by failure of the ducts to empty after a ten minute interval. Spasm of the duodenal musculature is indicated on the x-ray film by a narrowing of the lower end of the common duct to a sharp pencil point (6 in Fig 3A and B); this is not present in pictures taken one minute after five deep inhalations of amyl nitrite. Duodenal spasm may be indicated by roentgenographic study of the duodenum under a special method previously described.²

*Supplied through the courtesy of the Winthrop Chemical Company, New York City.

edly due to pressure within the pancreatic duct. It is complained of occasionally by sufferers from biliary tract disease, and tends to complicate the differential diagnosis between cholecystitis and peptic ulcer.

Unsuspected stones in the common duct can frequently be made to pass by applying the following procedure. Attach the pressure apparatus to the T tube and slowly raise the perfusion pressure to the level of toleration or to 500 mm. of water. Then have the patient take five deep inhalations

of amyl nitrite. Frequently the sudden release of spasm will allow the pressure of the saline solution to force the stone into the duodenum. This procedure may be repeated as often as desired until roentgenograms show disappearance of the stone.⁵

LATER CARE

About two weeks following operation the patient is instructed to begin clamping off the T tube. Starting with a half hour twice daily, the time is increased until the tube is clamped off all the time. If the patient experiences distention or

In the case of postoperative patients in which cholecystectomy was performed without T-tube drainage, we prescribe glyceryl trinitrate for nausea, distention or biliary colic. During the first few days after operation we use dilaudid freely for the control of pain. Any untoward symptoms caused by this drug may be neutralized by glyceryl trinitrate.

MEDICAL TREATMENT OF BILIARY-TRACT DISEASE

The patient who returns several months or years after cholecystectomy complaining of repeated at

FIGURE 4

A This is a choledochogram taken under resting conditions, showing moderate spasm at 6 and stricture of the ampulla of Vater at 2

B Following inhalation of amyl nitrite the spasm has disappeared at 6, the opaque medium has been allowed to flow freely into the ampulla of Vater and, finding obstruction at the duodenal mucosa, has regurgitated into the pancreatic duct. The patient experienced severe midepigastria pain at this time

pain during the clamping he is instructed to place one to two 1/250 gr tablets of glyceryl trinitrate under the tongue. If he does not obtain relief of pain in five minutes, the tube is unclamped and allowed to drain. The tube may be removed in three weeks or left in for six months, as indicated.

If the patient can keep the tube clamped off continuously for three weeks and be free of pain, it is safe to remove it, provided the pain level is above 300 mm of water, the resting pressure level is below 30 mm of water, and the roentgenograms show absence of stones and free emptying of the T tube. The patient is instructed to take glyceryl trinitrate as required for distention or pain.

tacks of typical biliary colic presents a problem to the surgeon. A diagnosis of biliary dyskinesia can usually be made by the characteristic location of the pain in the right subcostal region, extending around into the right scapular region. At times the pain reaches the tip of the shoulder, or it may extend down into the lumbar region and direct one's attention to the kidney. A test dose of morphine, 1/6 gr given subcutaneously, will usually bring on a characteristic attack of pain in five minutes to one-half hour. An induced attack is readily relieved by inhalation of amyl nitrite or by sublingual administration of one or two 1/250 gr tablets of glyceryl trinitrate.

In such cases we prescribe one or two 1/250 gr tablets of glyceryl trinitrate every three hours for three days, and one three times daily after meals and at bedtime for three weeks. This procedure keeps the pressure in the biliary system at a low level and promotes a free flow of bile into the duodenum. The patient is allowed a general mixed diet. Cooked fats and fried foods are eliminated. The patient is encouraged to take cream and eggs freely. This course of treatments produces permanent relief of symptoms in most cases. If this treatment fails, a second operation must be considered in order to explore the common bile duct for missed stones.

We have used similar treatment in cases of cholecystitis with gall bladders that fill and empty freely and do not contain stones. We have had 6 such cases with symptoms of cholecystitis for two to fifteen years, the patients varying in ages from twenty-two to sixty five years. After a course of treatment as outlined they have been entirely symptom-free for periods up to one and a half years. We have found this treatment useful for 4 patients with stone filled gall bladders, in whom a surgical procedure carried an increased risk because of advanced age, hypertension or coronary disease. All have been rendered symptom-free by a course of glyceryl trinitrate. They frequently report prompt relief of individual attacks after single doses. Two of these patients were moderately jaundiced when treatment was started. Icterus disappeared in a few days and has not returned. One patient has been symptom free for one year and the other for four months. One of the others has since had an attack of cerebral hemiplegia, proving the advisability of deferring operation.

We do not advise this treatment in cases of cholelithiasis except as a temporary procedure or when operation is contraindicated. We believe at present that a stone filled gall bladder or one which is not functioning should certainly be removed if the patient's condition permits.

SUMMARY

Biliary colic following cholecystectomy is due to obstruction of the common duct preventing the flow of bile into the duodenum. Obstruction of the common duct may be due to stone, stricture, edema or spasm. The back pressure results in pain. Common-duct pressure of 70 mm. of water produces pain in some individuals, while 500 mm may be withstood by others with impunity. Prolonged T-tube drainage allows the common duct to resist greater pressures. Glyceryl trinitrate relaxes duodenal spasm and tends to lower the resting intrabiliary pressure. Methods of studying the patency of the papilla of Vater and the condition of the bile ducts are described.

Biliary dyskinesia and many symptoms of cholecystitis are relieved by a course of treatment consisting of the daily use of glyceryl trinitrate to relax duodenal spasm.

of amyl nitrite. Frequently the sudden release of spasm will allow the pressure of the saline solution to force the stone into the duodenum. This procedure may be repeated as often as desired until roentgenograms show disappearance of the stone.⁵

LATER CARE

About two weeks following operation the patient is instructed to begin clamping off the T tube. Starting with a half hour twice daily, the time is increased until the tube is clamped off all the time. If the patient experiences distention or

In the case of postoperative patients in which cholecystectomy was performed without T-tube drainage, we prescribe glyceryl trinitrate for nausea, distention or biliary colic. During the first few days after operation we use dilaudid freely for the control of pain. Any untoward symptoms caused by this drug may be neutralized by glyceryl trinitrate.

MEDICAL TREATMENT OF BILIARY-TRACT DISEASE

The patient who returns several months or years after cholecystectomy complaining of repeated at

FIGURE 4

A This is a choledochogram taken under resting conditions, showing moderate spasm at 6 and stricture of the ampulla of Vater at 2.

B Following inhalation of amyl nitrite the spasm has disappeared at 6, the opaque medium has been allowed to flow freely into the ampulla of Vater and, finding obstruction at the duodenal mucosa, has regurgitated into the pancreatic duct. The patient experienced severe midepigastria pain at this time.

pain during the clamping he is instructed to place one to two 1/250 gr tablets of glyceryl trinitrate under the tongue. If he does not obtain relief of pain in five minutes, the tube is unclamped and allowed to drain. The tube may be removed in three weeks or left in for six months, as indicated.

If the patient can keep the tube clamped off continuously for three weeks and be free of pain, it is safe to remove it, provided the pain level is above 300 mm of water, the resting pressure level is below 30 mm of water, and the roentgenograms show absence of stones and free emptying of the T tube. The patient is instructed to take glyceryl trinitrate as required for distention or pain.

tacks of typical biliary colic presents a problem to the surgeon. A diagnosis of biliary dyskinesia can usually be made by the characteristic location of the pain in the right subcostal region, extending around into the right scapular region. At times the pain reaches the tip of the shoulder, or it may extend down into the lumbar region and direct one's attention to the kidney. A test dose of morphine, 1/6 gr given subcutaneously, will usually bring on a characteristic attack of pain in five minutes to one-half hour. An induced attack is readily relieved by inhalation of amyl nitrite or by sublingual administration of one or two 1/250 gr tablets of glyceryl trinitrate.

A left nephrectomy was performed an atrophic hydronephrotic kidney being removed without difficulty. The ureter appeared normal except at the ureteropelvic junction, where there was definite narrowing and evidence of chronic perireteral inflammation and fibrosis. No aberrant vessels were discovered. The pathological report was as follows:

The specimen consists of a kidney measuring 6 by 3 cm. The cortex is extremely rough and granular while the cut surface shows a replacement of the normal parts by numerous large dilatations of the calyces. Inflammatory changes are apparent in the walls. The function in this kidney had apparently ceased. The tubules are atrophic and there is a tremendous infiltration of mononuclear leukocytes, lymphocytes, plasma cells, neutrophils and eosinophils. A great deal of interstitial hemorrhage has taken place. Diagnosis: Chronic pyelonephritis and hydronephrosis.

This is the history of a 16-year-old girl with a seven year story of left lumbar pain, with one hospital admission because of pyuria, who was not studied urologically until seven years after the onset of symptoms. There was a combination of impaired development and kidney destruction, both of which might well have been obviated by judicious dilatation of the ureter and treatment of the infection when the signals of distress were first evident.

CASE 2. A. F., a 34-year-old married woman 5½ years previous to admission when 3 months pregnant, developed an attack of pain in the right kidney region accompanied by pyuria. She was hospitalized for 5 days, during which time an unsuccessful attempt was made to perform pelvic lavage. One and a half months later and again 2 weeks postpartum she suffered recurrences. These attacks were accompanied by chills, fever and nausea. Since then she had had about one attack of pain per year each attack lasting 3 or 4 days. Between attacks she had been symptom-free. No x-ray photographs had ever been taken. The last episode began 3 days before admission with a dull pain in the right costovertebral angle, radiating to the right upper quadrant of the abdomen. There was slight dysuria and the urine had become reddish.

Physical examination revealed no abnormalities. The urine showed a large amount of albumin but no sugar. The sediment contained many red and white blood cells.

Cystoscopy revealed a rather prominent right ureteral orifice with an orifice barely large enough to admit a No. 6 Fr catheter. Forty cubic centimeters of milky fluid was obtained from the right kidney pelvis and 3 cc. of clear urine from the left kidney pelvis. A phenolsulfonphthalein functional test showed no excretion on the right side. A culture of the urine from the right kidney was reported as positive for *Bacillus proteus* and one of that from the left as negative. Retrograde urography showed right nephrolithiasis, marked hydronephrosis and hydroureter involving the entire ureter down to the ureterovesical junction (Fig. 2).

A right nephrectomy and partial ureterectomy was performed. Only a moderate amount of perirenal reaction was encountered. In view of the proteus infection and the extensive involvement of the ureter a nephroureterectomy had been planned but the condition of the patient

did not warrant so extensive a procedure. Consequently a complete ureterectomy was postponed. The pathological report was as follows:

The specimen consists of a kidney and attached ureter. The latter is thick walled and tremendously dilated. The kidney is increased in size. The surface shows many fetal lobulations. The cut surface shows tremendous dilatation of the pelvis and calyces, which has converted the organ into a large, thin-walled cyst like structure. The wall of the pelvis is thick, granular and congested. The organ contains one large stone

FIGURE 2.

Note the extensive hydronephrosis and hydroureter

which measures 2.0 by 1.5 by 1.5 cm., and three smaller stones averaging 5 mm. in diameter. The kidney tissue weighs only 100 gm. Sections throughout the pelvis show a tremendous chronic inflammatory reaction. The glomeruli are engorged with blood, and the surrounding tubules exhibit granular degeneration. Throughout the medullary portion chronic inflammatory changes are visible. Diagnosis: Nephrolithiasis, hydronephrosis and chronic ascending interstitial nephritis.

Two and a half weeks postoperatively specimens of bladder urine and fluid from the right ureter while showing numerous white cells, were negative on culture. Accordingly ureterectomy was postponed in order to see whether the pyuria could not be controlled by other measures. Three months later the patient was symptom-

free, and the urine showed only occasional white cells. Apparently ureterectomy will not be necessary.

This case had a five-and-a-half-year history of renal pain and chronic infection. Adequate treatment of the infection and dilatation of the ureter early in the course of the disease might well have averted this sequence of events.

CASE 3 H N, a 41 year-old, married woman, 8 years previous to admission began having attacks of sharp pain over the left lower ribs in the axillary line. The pain did not radiate to the flank or costovertebral angle, nor was it

FIGURE 3

Note the large kidney with massive dilatation of the calyces

influenced by respiratory movements. It was severe enough at times to cause perspiration. The attacks lasted half a day and recurred every 3 months to 1 year until 4 years previously, since when there had been only minor episodes of pain in this area. There were three episodes of transitory gross hematuria following attacks of pain. No history of dysuria, frequency or nocturia was obtained. The patient was referred to the hospital for study because of pyuria and a systolic blood pressure of 160.

Examination, except for hypertension, was not remarkable. The urine showed a slight trace of albumin and a sediment containing innumerable white blood cells.

Cystoscopy showed a normal bladder mucosa. The ureteral orifices and bladder neck appeared normal. A No. 6 Fr catheter was passed to the right kidney pelvis. A catheter could be passed only about halfway to the left kidney pelvis. No residual urine was aspirated from either side. The urine from the right kidney pelvis was normal, that from the left ureter showed many white blood cells.

A phenolsulfonephthalein test was normal on the right side, and zero on the left. Culture of the urine from the left ureter was negative, that of the bladder urine showed streptococci. Retrograde pyelography revealed a sharp angulation of the left ureter at the level of the fourth lumbar vertebra, beyond which neither catheter nor Diodrast solution passed. What appeared to be a greatly enlarged kidney shadow extended from the iliac crest to above the 11th rib. Intravenous pyelography showed faint, widely separated splotches of media characteristic of extensive hydronephrosis (Fig. 3).

Nephrectomy was performed, a large, hydronephrotic kidney being removed. Immediately below a greatly dilated pelvis there was an S-shaped kinking of the ureter, which was maintained by adhesive bands, thereby forming a marked obstruction to the ureteral flow. This obstruction was located at about the level of the 4th lumbar vertebra. The pathological report was as follows:

The specimen consists of a kidney which has been very largely converted into a series of cyst like pockets, all of which are filled with a blood tinged fluid. The renal parenchyma has thereby been reduced to a small rim of tissue except at the lower pole, where an intact portion measuring 2 by 2 cm remains. The thin rim of the cortex shows atrophy of the glomeruli and tubules, and heavy round-cell infiltration. Diagnosis: Hydronephrosis, with chronic inflammation.

This case presents an eight-year history of some what atypical renal pain, with three attacks of gross hematuria (not even hematuria induced her to seek adequate study) and eventual destruction of the kidney due to ureteral obstruction and infection. A nephropexy with a lysis of adhesions might have overcome the obstruction if undertaken early enough. However, only the end result was observed, and the low position of the kidney may well have been due simply to its enlargement. As a result, it is difficult to say what operative measures would have been necessary, but certainly they would have been no more radical than those that were ultimately adopted. This patient was originally on the medical service for study of her hypertension. The presence of pyuria and the history of the case suggested the possibility of hypertension due to unilateral renal disease and hypertension. However, the blood pressure became normal soon after admission and before operation. Following discharge from the hospital the hypertension recurred.

CASE 4 H H, a 45 year-old man, complained of painless hematuria of 1 week's duration. He had no other complaints, aside from a feeling of lassitude. For the last 31 years he had had numerous attacks of colicky pain in the left costovertebral region and left flank, unaccompanied by chills, fever or symptoms of bladder irritation. These attacks were severe enough to require repeated injections of morphine. So far as he knew, his urine had never shown anything abnormal. No urological studies had ever been made.

Physical examination gave essentially negative results. Cystoscopy revealed a normal bladder, with grossly bloody fluid issuing from the left ureteral orifice. Retro-

grade pyelography showed kinking of the ureter and distortion of the renal pelvis by what appeared to be a tumor mass. Hydronephrosis was also present (Fig. 4)

At operation a slightly enlarged kidney was found.

FIGURE 4

Note the deformity of the renal pelvis and calyces and the presence of a ureteropelvic stricture

The pelvis was greatly distended by a large intrapelvic mass, which proved to be a large papilloma with malignant changes at its base, and was reported by the Massachusetts Tumor Diagnosis Service as epidermoid carcinoma. A

two-stage nephroureterectomy was performed. The ureter showed no involvement.

The patient was apparently well 1½ years after the operation but there has been no follow-up cystoscopic examination to check the possibility of bladder implants. The urine was negative except for the slightest possible trace of albumin.

The evidence in this case is, of course somewhat presumptive, but it seems reasonable to suppose that sometime during the thirty-one year period of recurrent left renal pain it would have been possible to remove this kidney in its precancerous state.

Sir Thomas Lewis* has said of pulsus alternans "It is the faint and anguished cry of a fast failing muscle, which, when it comes, all should strain to hear, for it is not long repeated. A few months, a few years at most, and the end comes." This clinical metaphor may well be applied to renal pain, for though the latter requires no straining for an audition when it comes, it too is the anguished cry of an organ that is failing, or may fail. And having been heard, it should be heeded, for unlike the helpless voice of pulsus alternans, this voice is a cue which may render possible the rescue of an organ or an individual from an insidious death.

SUMMARY

The end results of four cases in which renal pain was allowed to recur unheeded are herein illustrated. That these cases came to light on a small urological service within a short period of time suggests the number of similar cases which probably occur in the country at large.

With this in mind, a reiteration of the results of failure to investigate renal pain appears to be warranted.

CLINICAL NOTE

AN INGESTED FOREIGN BODY
IN THE BUTTOCK*

Report of a Case

PERCY A. BROOKE, MD†

WORCESTER, MASSACHUSETTS

INJURIES to the lower part of the rectum and anal canal from foreign bodies are caused either by objects' being introduced into the rectum by

of these report the actual presence of foreign bodies in the rectum rather than give information as to the damage that can be inflicted by them on the rectum, anus and surrounding tissues. The majority of objects referred to in these reports had been inserted into the rectum from below and were found free in it. So far as I know, there are no cases on record in which an ingested foreign body had pierced the rectal or anal walls and lodged in the tissues external to the rectum.

Two cases are cited, however, in which foreign bodies introduced into the rectum were found in the perirectal tissues and not in the lumen. Say

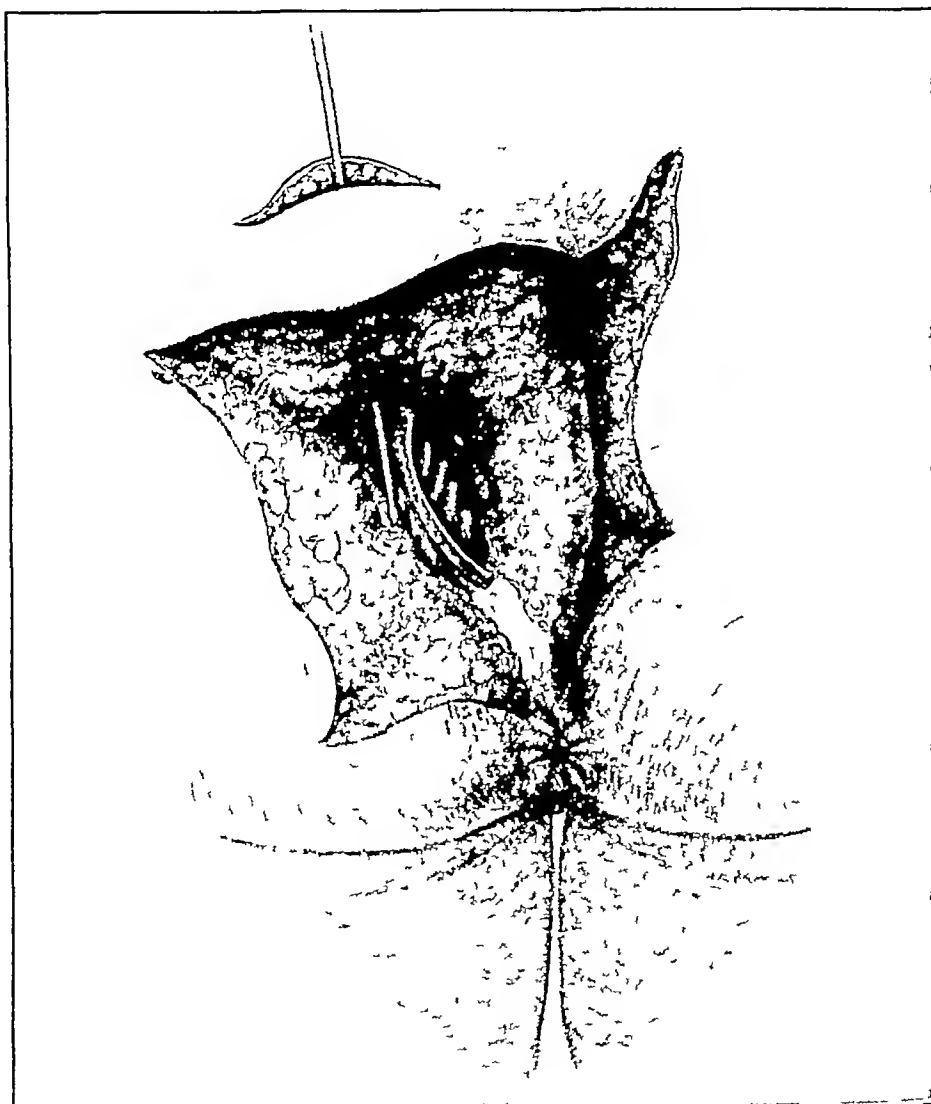

FIGURE 1

way of the anus or by injurious substances or articles ingested with certain foods.

A review of the literature of the last twenty years has shown a fairly large number of papers dealing with foreign bodies in the rectum. Most

ers¹ removed a wooden penholder from an abscess in the tissues adjacent to the coccyx, the object having been introduced into the rectum by the patient as an erotic act. Landsman² cited a case of encysted foreign body in the rectum that was mistaken for a malignant tumor.

This paper reports a case of a localized abscess,

*From the Department of Proctology, Worcester City Hospital.

†Proctologist, Worcester City Hospital and Memorial Hospital, Worcester.

an anal fistula and an encapsulated mass, somewhat superficial and posterior to the left ischio-rectal space, subsequent to the ingestion of a chicken bone. The foreign body was found in the tissues of the buttock in a glistening, encapsulated cavity, which had been ruptured by a recent injury to the tissues superficial to the cavity

CASE REPORT

A 47 year-old woman called to see Dr N S Scarcello, of Worcester complaining of tenderness in the left buttock, which was preceded by a fall 2 days previously. The patient was advised to take hot sitz baths. About 1 week later she said that the night before she had had chills and felt feverish and that a painful lump had developed near the point she struck when she fell. The patient was referred to me on October 31 1939.

Examination revealed a large, brawny indurated area in the left buttock about 4 cm. from the anal margin and posterior to the position of the left ischio-rectal space. At the mucocutaneous line in the left posterior quadrant was a hypertrophied papilla and a patent crypt into which a bent probe could be easily inserted. The temperature was 102° F. The patient was sent to the Worcester City Hospital.

Under spinal anesthesia an incision was made into the indurated area and a considerable amount of yellowish, creamy pus was evacuated. The resulting cavity did not penetrate deep into the ischio-rectal space, but extended posterior and lateral from it. A fistulous tract was discovered having its origin in the crypt mentioned above and extending laterally toward the cavity for 3 cm. There an encapsulated mass 6 cm. long and 2 cm. wide was found. Projecting from the medial end of this mass was the end of a chicken bone (Fig. 1). After the mass had been opened the bone was removed. It measured 5 cm. long, and one end was shaped like a harpoon. It was evidently the top part of the breast bone. The inside of the mass was glistening and reddish white. Orifices in the cavity were several tracts. These were opened up and the overlying tissue was removed, since it appeared to be very abnormal. At the top part of the encapsulated orifice was a passage into which a probe was

inserted. This probe proceeded outward for 3 cm. and then approached the surface. A stab wound was made in the skin and the probe reached the surface at this point.

The usual aftercare was carried out, and 6 weeks after the operation the cavity had closed and all the wounds had healed.

The patient denied having inserted any foreign body into the rectum and there was no apparent reason for doubting her story. On the other hand, she did not remember having swallowed a bone.

The discovery of foreign bodies in the rectum is not unusual. It has been pointed out that mode of entrance is more frequently from below than by way of the gastrointestinal tract. There are three things about this case that make it unusual: first, that it was possible for a person to swallow a chicken bone 5 cm. long and sharp at both ends and not be aware of the fact, secondly, that this object traversed the entire gastrointestinal tract, apparently without doing harm, and pierced the lower rectal and anal walls without discomfort to the host and thirdly, that the foreign body resided in an encapsulated cavity which failed to cause the slightest bit of trouble to the host until she fell and ruptured the capsule.

SUMMARY

The case is reported of an ingested chicken bone removed from the tissues of the left buttock. The bone traversed the entire gastrointestinal tract and pierced the rectum immediately above the mucocutaneous line. Six weeks after operation the wound had completely healed.

REPORT ON MEDICAL PROGRESS

PHYSIOLOGY*

HEBBEL E. HOFF, M.D.†

NEW HAVEN, CONNECTICUT

THREE publications merit mention as indications of progress in physiology. The first is the twentieth volume in the series of research publications of the Association for Research in Nervous and Mental Disease,¹ devoted this year to the hypothalamus and central levels of autonomic function. A large volume of nearly a thousand pages, it is divided almost equally into sections on anatomical, physiological and clinical studies. A very complete bibliography is included, as well as a short historical account by Fulton. Frohlich's original description of the adiposogenital syndrome is reprinted, it might have been made more accessible by translation into English. The second book is the short monograph by Barnes² entitled *Electrocardiographic Patterns*. Based on material presented at the meeting of the American Medical Association in 1937, it is notable for the careful correlation of electrocardiographic tracings, clinical history and pathologic findings. It exercises a valuable influence in insisting on the study and evaluation of all the various leads in the diagnosis of cardiac infarction, rather than dependence on some unusual lead of supposedly special virtue. The monograph is noteworthy for the clearness and good use of illustrations, and for the introduction in a later chapter of the subject of the electrocardiogram in pericarditis.

The *Selected Writings of Sir Charles Sherrington* issued under the editorship of Denny-Brown,³ is a particularly well-planned tribute to Sir Charles Sherrington. It outlines the history of his researches in the words of some of his most significant accomplishments, and represents in reality the history of an era in neurophysiology. Sherrington's pupils will find the volume an old friend, and will wish only that still more of the story could have been told, and many more excerpts included. To all physiologists and neurologists it will increase the availability of the writings of Sherrington, which constitute so much of the past and so much of the foundation for the future.

THE "RESPIRATORY CENTER"

It has been generally accepted that the rhythmic movements of respiration are initiated by the au-

tomatic activity of a bilateral group of cells lying in the medulla. These cells have been considered to act as a sort of pacemaker for respiratory activity in much the same fashion as the sinoauricular node acts as the pacemaker for the heart, and they are classically—and loosely—termed the "respiratory center." The work of Bronk and Ferguson⁴ indicates the general nature of this nervous discharge. Each contraction in an inspiratory or expiratory muscle is the result of a short burst of impulses in each motor unit, variations in depth of respiration are the result of variations in the frequency of discharge from the individual nerve cells, the duration of this discharge and the number of nerve cells in action. The discharge of impulses in expiratory and inspiratory neurones is under reciprocal control, so that the two alternate phasically. This discharge continues after the vagus nerves have been cut and phasic proprioceptive impulses have been interrupted by curarization. Gesell^{5,6} has shown that neurones in the medullary respiratory center originate this activity. He has summarized the evidence in support of the view that these neurones are spontaneously rhythmic, and are truly the pacemaker of the respiratory rhythm. Normal rhythmic activity continues after procedures that seem completely to deafferent the respiratory center, namely section of the vagus, deafferentation of cervical and cranial nerves or complete curarization, which stops phasic activity in the muscle proprioceptors. A very strong argument in favor of spontaneous rhythmicity of the respiratory center is the observation by Adrian and Buytendijk⁷ of slow rhythmic potential changes in the isolated brain stem of the goldfish, which closely parallel the respiratory rhythm in the intact fish.

There is, however, evidence that the origin of respiratory rhythm is not so simple as this, and it is furnished largely by recent review of the very interesting papers of Marckwald^{8,9} in 1887 and 1890. Stella¹⁰ and especially Pitts, Magoun and Ranson¹¹⁻¹³ deserve credit for calling attention to the significance of Marckwald's observations. The experimental evidence, in the essentials of which all these authors agree, may be stated briefly. There is, in the medulla, a bilateral group of cells over the inferior olive which controls inspiration

From the Laboratory of Physiology, Yale University School of Medicine.
†Associate professor of physiology, Yale University School of Medicine.

Stimulation of this inspiratory center produces inspiratory effort, continuing as long as the stimulation is maintained. The animal may be killed by asphyxia by thus throwing it into a prolonged inspiratory spasm. Slightly above the center for inspiration is an expiratory center, where stimulation produces a maintained expiration. The decerebrate cat breathes practically normally, even when the vagi are cut. If the section of the brain stem is made at a somewhat lower level, namely just below the upper part of the tegmentum of the pons, but still well above the medullary respiratory center, the animal breathes normally so long as the vagi are intact. When the vagi are then cut, or blocked by cold, the animal goes into a prolonged inspiratory spasm. Although this inspiratory spasm ("apneusis") may occasionally be broken by short pauses, there is no appreciable expiration, and the animal dies from asphyxia.

From these experiments Pitts, Magoun and Ranson conclude that the medullary respiratory center is not spontaneously rhythmic, but if completely isolated from outside influence gives rise to a constant discharge from the inspiratory center, the intensity of which depends on the carbon-dioxide content of the arterial blood¹⁴, and that this constant discharge is periodically inhibited in one or both of two ways. Afferent impulses in the vagus, arising because of the stretch of the bronchi in inspiration,¹⁵ may serve to convert the constant into an intermittent discharge. There is also a center higher up the brain stem, presumably in the upper part of the tegmentum of the pons, which can do the same thing. Either the vagus or the pontine center may alone operate to render periodic the constant activity of the medullary respiratory center. The pontine center does not seem to be influenced reflexly, and it is still problematical how it operates to produce the periodicity it imposes on the primitive respiratory center. It may again be spontaneously rhythmic, and there is evidence from the work of Gasser that single nerve fibers may give rise to this type of periodic activity.¹⁶ On the other hand, Pitts, Magoun and Ranson decide on anatomical grounds that there is probably a reciprocal relation between the medullary inspiratory center and the pontine center, so that activity in the one inhibits the other, and vice versa, and a type of circus movement is set up which keeps the two centers in a state of alternating activity. Whatever the explanation, these experiments are of the greatest importance in calling renewed attention to the existence of a brain-stem center lying above the medulla, which must now logically be considered as an integral part of the "respiratory center."

THE ORIGIN OF PHASIC MOVEMENTS

An interesting counterpart of the work reported here on the rhythm of the respiratory center is found in recent papers by Smith Mettler and Culler.^{17, 18} These workers found that in the cat two types of response may be elicited by faradic stimulation of the cerebral cortex, a phasic and a tonic reaction. They report that the phasic type of response can be elicited only in an animal in which the dorsal roots as well as the ascending ventral spinocerebellar tracts are intact. When this afferent pathway is interrupted, stimulation of the cortex yields only a tonic or maintained contraction. They conclude that the stimulation of the cortex sets up a constant discharge from the neurones in the motor root unless it is periodically inhibited by impulses originating in the muscle proprioceptors.

This view, as the authors themselves point out, is at variance with evidence concerning other phasic movements. Sherrington^{19, 20} noticed in 1906 that the scratch reflex in the decerebrate or decapitate dog and cat proceeds even more briskly than normal after the limb has been deafferented. Graham Brown²¹ demonstrated that phasic running movements may be initiated in an isolated spinal segment that is completely deafferented. It is, of course, a matter of observation that phasic movements may be executed by the tabetic limb, and monkeys execute phasic movements with hind limbs that have been deprived of sensation by appropriate section of the dorsal roots.

MUSCLE HEMOGLOBIN

A review by Millikan²² on muscle hemoglobin calls attention to an important phase of respiration not always sufficiently emphasized. This substance, closely related to the hemoglobin in blood is partly responsible for the red color of muscles, and differences in its concentration are responsible for the difference between "pale" and "red" muscles. It has been known for some time that distinct differences in physiologic behavior are associated with the difference in color of the muscle. Red muscles operate more slowly, maintain contractions over longer periods with less fatigue than do pale muscles, and have a slower time of reaction. Examples of red muscles are the heart muscle of large mammals, the wing muscles of large flying birds and the leg muscles of running animals, such as the horse and the dog. Muscles which contract more frequently have less hemoglobin and are pale. An extreme example is the wing muscle in flying insects, which may contract as often as three hundred times per second. The hearts of small birds and small mammals,

such as mice, also contain smaller quantities of hemoglobin. Some muscles, such as the heart and leg muscles of the frog, contain no muscle hemoglobin. In the cat, one of the muscles of the calf (soleus) is red while the other (gastrocnemius) is pale. The twitch of the soleus muscle is more prolonged, it gives a more smoothly fused tetanus, full tetanus is maintained with fewer impulses per second, and it fatigues less readily. It is therefore fitted for economical maintenance of tension over long periods of time, as in standing. The gastrocnemius muscle, on the other hand, gives a shorter but more vigorous twitch, and is consequently adapted for short acting but strenuous activity, such as running. The same muscle may show a gain in muscle hemoglobin following increased activity.

The concentration of muscle hemoglobin is much less than that of hemoglobin in the blood. Thus the maximum concentration of muscle hemoglobin in the heart of the dog is nearly 500 mg per 100 gm of tissue, while the concentration in the blood may be as high as 18,200 mg per 100 gm. The total oxygen capacity of all the muscle hemoglobin in a man has been calculated at 345 cc, while the blood could hold 1160 cc.²³ Millikan has calculated that in the normal dog's heart the amount of oxygen available in combination with muscle hemoglobin would be used up in about seven seconds of normal activity, or in less than a second of extreme activity. The substance is obviously therefore able to act only as a short-time source of oxygen.

The properties of muscle hemoglobin favor its storage function. It has a greater affinity for oxygen than has blood hemoglobin, so that, even at the venous end of the capillaries, stores of muscle hemoglobin will be full while the blood will be seriously depleted of oxygen. On the other hand, it appears that the cell oxidase systems can on their part operate at a still lower oxygen tension, and in turn deplete the oxygen stored in muscle hemoglobin.

The ability of muscle hemoglobin to store oxygen and deliver it to the cells at a later time seems now to explain the unusual ability of some animals to dive for prolonged periods. Men and other non-diving mammals can hold their breath for only a minute or so if respiration is shut off without any preparation. Here the limiting factor is probably the accumulation of carbon dioxide. When the breath is held after a period of forced breathing, respiration can be suspended for as much as five minutes or slightly longer. The limiting factor is the oxygen capacity of the body, and it can be calculated that the breath can be held

only as long as it takes to use up the oxygen in the blood, tissue fluids, lungs and muscle hemoglobin. If the lungs are filled with pure oxygen after forced breathing, three or four liters more of oxygen are made available, and some experimenters have been able to hold their breaths for as long as fifteen minutes.

These are relatively short periods when compared with times for diving mammals. Some whales may remain submerged for two hours, and seals, muskrats and beavers regularly make dives of fifteen minutes. It must also be remembered that they do not remain at rest, but may show considerable activity. At least one clue to this behavior is the discovery by Robinson²⁴ that the muscle of the seal contains eight to ten times as much muscle hemoglobin as is found in the muscle of non-diving mammals. Irving²⁵ has discussed the other mechanisms that may also operate to facilitate endurance while diving.

Millikan's work makes necessary a reconsideration of the generally accepted views concerning the chemistry of muscular contraction. These hold that the energy for muscular contraction is derived principally from the anaerobic breakdown of certain substances found in muscle, and that during rest these compounds are resynthesized, with energy derived from oxidation. The process may be likened to a storage battery, which provides a readily available source of energy, but must be recharged between periods of use. Three separate anaerobic reaction systems have been postulated as the source of the energy for contraction. The first of these was the breakdown of glycogen to lactic acid. Later Lundsgaard²⁶ showed that contraction still occurred after the breakdown of glycogen to lactic acid was prevented by poisoning the muscle with iodoacetic acid, and proposed the hydrolysis of phosphocreatine as the source of the energy. Still later the hydrolysis of adenosine triphosphate was suggested as the primary process. In recent years Sacks and Sacks²⁷ have brought forward certain objections to the theory of anaerobic mechanisms, and have proposed that the fundamental reactions in contracting muscle are oxidative and not anaerobic, and that anaerobic reactions take place only when the oxygen supply is inadequate to support a fully aerobic metabolism. Their arguments are based largely on the time required to resynthesize the precursors of the anaerobic metabolites. Naturally, the rate of resynthesis of these substances must be rapid enough so that it can account for their nonappearance during light exercise with an adequate oxygen supply. Actually, the lactic acid cycle does not meet these requirements, and in fact a muscle

with an intact blood supply does not resynthesize lactic acid at all, but lets it escape into the circulation to be resynthesized in the liver or the heart. Sacks²⁷ has recently demonstrated that oxidative resynthesis of the other two substances does not proceed fast enough to permit the establishment of the steady state."

Millikan has now been able to show that muscle hemoglobin begins to give up its oxygen within a fifth of a second after the onset of tetanic contraction, and fully regains it in a few seconds after cessation of the contraction in the presence of an adequate blood flow. This rapid utilization of oxygen seems to account for the greater part of the total oxygen demands of the contraction. Millikan concludes

The acceptance of these results does not necessarily mean the abandonment of the classical theory of anaerobic contraction and oxidation recovery. It does, however, mean something nearly as catastrophic, namely that none of the reactions of anaerobic muscle biochemistry seem to be of much importance for aerobic activity. The theory that a direct oxidative process provides the energy for contraction was proposed by Sacks in 1932. Since the ability of muscles to operate for a time anaerobically is unquestioned this hypothesis requires a dual mechanism, one, a normal aerobic quick, efficient mechanism the other an emergency oxygen-debt mechanism, presumably of lower efficiency called into action when there is an oxygen lack. In terms of the well known analogy the muscle can run off its batteries if it has to charging them up afterwards, but it prefers to operate by direct drive if it can.

HEPARIN

The monograph on heparin by Jorpes²⁸ calls attention to renewed interest in a substance that has been known as a potent anticoagulating agent since its discovery by Howell in 1916, but which has only recently been made available for extensive study by the improved methods of recovery developed by Charles and Scott and cited by Best.²⁹ Named heparin because of its abundant occurrence in the liver, it is now known to be present throughout the body. It unites in vitro and in vivo with highly basic dyes, especially toluidine blue. With this dye it gives a strong purple stain in vivo, and the dye can therefore be used to stain histological preparations and detect its presence. This technique shows that heparin is present in large quantities in the mast cells of Ehrlich, and it is presumed that these cells secrete the material into the blood stream. This possibility seems strengthened by the position of the mast cells around the capillaries and small nonmuscular blood vessels.

The anticoagulating activity of the most recent crystalline compounds is about 100 units per milligram, that is, 1 mg. will protect 100 cc. of blood from coagulation for twenty four hours. In man

1 mg. per kilogram of body weight will prolong the coagulation time to twenty or thirty minutes. There is still some question about the harmlessness of the substance. In dogs it has been difficult to detect any harmful effects, even when administered in large quantities over several days. In man it has been used extensively, with few untoward results, but there are some reports of arterial hemorrhages following its use.

The mechanism of the action of heparin is still disputed.³⁰ Howell's original conclusion was that it prevented the activation of prothrombin, but there are some workers who claim that it prevents the reaction between thrombin and fibrinogen.³¹ Wherever it may function, there seems to be general agreement that it acts because of its high electronegative charge. This view is supported by the discovery of anticoagulant activity in other compounds of great molecular weight possessing high ionic charges.

Heparin has not yet been assigned any definite function in the normal organism, although the situation of the mast cells suggests that it may act to prevent thrombus formation in the small vessels. It may also operate to maintain the fluidity of other body fluids. The liberation of heparin into the blood stream in peptone shock in dogs has been shown to cause the increased coagulation time in this condition.

Clinically heparin has been used in a variety of conditions, obviously its employment has been at times injudicious, especially when the not too remote possibility of arterial hemorrhage has not been kept in mind. There is, however, an obvious reason for its employment in diseases complicated by thrombosis. Here the damage caused by the lesion responsible for the thrombus formation may be relatively unimportant, while the real damage is done by growth of the thrombus or by embolism. Some of these circumstances are reviewed by Jorpes and by Best.²⁹ More recently Kelson and White³² have reported successful treatment of subacute bacterial endocarditis by the combined use of heparin and sulfapyridine. The definite possibility of cerebral hemorrhage³³ cannot be considered a contraindication to this treatment in a disease that has previously been invariably fatal.

THE CARDIOVASCULAR SYSTEM

An excellent paper by Blumgart, Schlesinger, and Davis³⁴ contributes basically to the anatomy, physiology and pathology of the coronary circulation and presents a unified concept of the clinical manifestations of inadequate cardiac circulation. Extending the earlier observations from the same laboratory this paper arrives at the following con-

clusions In normal hearts the coronary arteries are anatomically and physiologically end arteries While smaller vessels have rich anastomoses with one another, as shown by the ready passage of watery injection materials from one coronary artery to another, the failure of mixing when more viscous injection masses are employed demonstrates the absence of anastomoses of a diameter of 40 microns or greater There is no development of anastomoses with age, in the absence of disease of the coronary arteries Obstruction to normal coronary arterial blood flow by narrowing or occlusion results regularly in the development of intercoronary anastomoses measuring 40 to 200 microns in diameter These anastomoses may compensate so well for the deficiency in coronary supply that the circulation remains adequate for ordinary activities, and no signs of necrosis or infarction can be found Myocardial infarction results from a disproportion between the demand for blood and its supply It may be produced by an excessive demand for blood in the presence of a reduced supply adequate for normal demands, or may follow reduction of blood supply below even minimal demands The absolute necessity for immediate and complete bed rest, sedation, reduction of excessively high heart rate and other measures designed to reduce the work of the heart in coronary occlusion is emphasized as a measure that may very possibly limit greatly the extent of myocardial necrosis, or even prevent its development Lack of oxygen supply to the myocardium may develop following causes other than narrowing or occlusion of the coronary vessels, for example fall in blood pressure, as in shock, and lack of oxygen-carrying capacity of the blood, as in anemia These factors must be closely watched in patients whose coronary insufficiency renders them more than usually vulnerable to oxygen lack In addition to these and other very important considerations, the paper raises a great many questions to be answered only by future work The mechanism of development of the arterial anastomoses and the rate at which they become established are important points about which the authors will no doubt have more to say in later communications

The fertile suggestions of Goldblatt continue to dominate the study of renal hypertension, and much new work has been reported Katz and Steinitz³⁵ have shown, by the elegant technic perfected by Hamilton, Woodbury and Vogt,³⁶ that renal hypertension in dogs is not accompanied by changes of the pressure in the pulmonary circulation Rodbard,³⁷ working in Katz's laboratory, has shown by the ingenious procedure of anastomosis of the ureter to the lumbar vein that the nor-

mal kidney does not prevent hypertension by excreting the hypertensive substance liberated by an ischemic kidney, but antagonizes its action by virtue of its own metabolic activity He suggests that the kidney destroys the pressor substance, but another equally possible hypothesis seems supported by two other reports Harrison, Grollman, and Williams³⁸ and Page and Helmer³⁹ present evidence that the normal kidney secretes a substance which does not by itself alter the normal blood pressure, but will lower the pressure in renal hypertension and antagonize the action of pressor substances obtained from the kidney MacLachlan and Taylor⁴⁰ have studied the suggestion that the hypertension which follows renal ischemia is an adaptive mechanism in which the kidney controls its blood flow in accordance with functional demands They have been able to show that an animal with mild hypertension produced by placing one kidney in a cast and removing the other responds to an increased protein intake in the diet by an increase in its blood pressure and by an exacerbation of hypertensive symptoms

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26231

PRESENTATION OF CASE

First Admission A thirty-eight-year-old building inspector was admitted to the hospital complaining of dyspnea on exertion of nine weeks' duration.

Three years before this first admission (twelve years before his death) two teeth became "infected" and the joints of both ankles and knees became exquisitely tender to pressure and motion. All his teeth were removed and a few weeks later his illness cleared, but complete recovery required six months. He was well until about nine weeks before his first admission, when he suddenly became dyspneic and felt exhausted while climbing three flights of stairs to his home. He ate supper and immediately noted a feeling of great epigastric distention. He went to bed and fell asleep. Three hours later he awoke with a knifelike pain in the epigastrium over an area measuring 8 to 10 cm. After about two hours the pain shifted to the lower abdomen and radiated to the right groin and right testicle but disappeared in about six hours. A physician gave him digitalis. A second identical attack occurred three weeks later. A third attack occurred two days before admission, and he vomited every two hours for about twenty-four hours. The vomitus was clear and had no taste. There were no other symptoms. A tonsillectomy and adenoidectomy were performed three weeks before admission.

The family, marital and past histories were non-contributory.

The physical examination revealed a well-developed and slightly obese man propped up in bed in moderate respiratory distress. The skin was warm and dry and showed numerous telangiectatic spots scattered over the abdomen and trunk. No definite petechiae were seen. The scleras were clear. He was pale with slight cyanosis and a cyanotic flush over the cheeks. The throat was injected, and the tonsils were absent. The chest showed a prominence of the left side, and a precordial impulse was definitely visible in the axilla. The apex of the heart was definitely enlarged toward the left in the anterior axillary line, and there was slight enlargement toward the right with some widening of the supracardiac dullness. The rate was

rapid, absolutely irregular, with a pulse deficit which prevented accurate timing of murmurs. The force of the beat varied in intensity. The first heart sound was partially obliterated by a rough, short presystolic and a systolic apical murmur. The second sound was reduplicated and clicking, but there were no murmurs at the pulmonic or aortic areas. The peripheral vessels were negative to palpation. The blood pressure was 160 to 120 systolic, 105 to 70 diastolic. The lungs showed many moist rales at both bases, especially the left, but the breath sounds were otherwise normal. The remainder of the examination was negative.

The temperature was 100.2°F, the pulse at the apex 140 and at the wrist 86. The respirations were 25.

Examination of the blood showed a red-cell count of 4,600,000 with a hemoglobin of 70 per cent (Sahli), and a white-cell count of 20,800 with 85 per cent polymorphonuclears, the smear was normal. Urine examinations showed + albumin, 35 to "rare" red blood cells and 10 to 5 white blood cells per high power field in the sediment, with occasional granular and hyaline casts. The stools were negative. The blood Hinton and Wassermann tests were negative. The serum non-protein nitrogen was 33 mg per 100 cc.

The patient was digitalized, though it was stated that he did not respond in the "usual way" in that the ventricular rate was difficult to control. With bed rest and supportive care, the temperature fell to normal on the fifth day. There was a slight pulse deficit, but otherwise he seemed improved and was discharged on the fifteenth hospital day.

Second Admission (five years later) Following discharge the patient was well and active until six months before his second hospital admission when he developed recurrent furuncles and abscesses involving the neck and buttocks.

Physical examination now showed a soft blowing diastolic murmur along the left sternal border in addition to the other findings noted above. Except for a white-cell count of 14,000, the laboratory findings were normal. A sugar-tolerance test was normal. He was discharged on the seventh day after dermatological therapy.

Third Admission (six weeks later) He was admitted for treatment of a rectal fissure which was successfully excised without complications.

Fourth Admission (fifteen months later) The patient entered with a "respiratory infection." Sticky rales were heard over the left lower chest, but no heart failure signs were elicited. With bed rest, a slightly elevated temperature fell to normal, and he was discharged after one week's stay in the hospital.

Final Admission (three years later, twelve years after the onset of his first symptom) Seven months before this admission, the patient noted the sudden onset of severe right costovertebral pain, which radiated to the right groin and to the right testicle. The pain was severe and associated with nausea and vomiting, it was of a cramplike or stabbing nature and remained almost constant for two days and then gradually disappeared, with some residual soreness. There was no dysuria or hematuria. Following this episode the patient was well until the day before admission, when he again had the onset of severe right flank pain. At this time it remained high and did not radiate to the testicle. The pain was again stabbing, severe, and associated with nausea and vomiting. It was almost constant until he was given a hypodermic injection for relief. He was then admitted to the hospital for study.

Physical examination revealed a well-developed and well-nourished plethoric man complaining of spasms of right flank pain referred to the suprapubic regions. The heart apex was seen and percussed at a level 4 cm. beyond the midclavicular line in the fifth interspace. The rhythm was totally irregular, but there was no pulse deficit. There was a rough systolic murmur at the apex with a loud, late, long, presystolic murmur also at the apex. A rough low pitched systolic murmur was heard at the aortic area, and a moderately loud blowing diastolic murmur was present along the left sternal border. The pulmonic second sound was much louder than the aortic second sound. No thrills were felt. The blood pressure was 166 to 120 systolic, 80 diastolic. There was no evidence of congestive failure. Tenderness was elicited in the right costovertebral angle with protective muscular spasm. There appeared to be slight tenderness over the course of the ureter to a point just above the pelvic brim. The spleen and liver were not palpable.

Examination of the blood showed a red-cell count of 5,400,000 with a hemoglobin of 15 gm (photoelectric-cell technic) and a white-cell count of 9800 with 77 per cent polymorphonuclears. Examination of the urine showed albumin which varied from ++ to ++++. The urine contained normally up to 1022. The sediment of all the specimens contained a few red blood cells. The nonprotein nitrogen was 65 mg per 100 cc. Intravenous pyelograms on the sixth hospital day showed no evidence of excretion of the dye on either side. A barium enema was negative.

On the eighth hospital day he was awakened by pain poorly localized under the left ribs and in the left upper quadrant. It was cramplike

in character and seemed to be related to gas. Palpation revealed no unusual masses or tenderness. No friction rubs were heard. Two hours later his condition became rapidly worse, the outstanding signs were those of peripheral shock. He was cold and sweaty. The blood pressure rose temporarily to 220 systolic, 80 diastolic and later subsided to its previous level. Numerous medium rales appeared over the upper chest on both sides, most prominent below the clavicles. There were slight impairment of resonance, and increased tactile fremitus and whispered voice. The lung bases remained relatively clear. In spite of the abrupt appearance of these signs in the lungs, there was no wheezing, cough or hemoptysis, no pain, and no obvious air hunger or cervical vein engorgement. The pulmonary second sound remained unchanged (moderately accentuated). A portable film of the chest showed that both upper lobes of the lungs contained a diffuse, symmetrical, mottled density extending to the apex and ending rather abruptly in the mid lung field. The lower lobes were clear. The right lower lobes seemed more radiant than usual. The heart was prominent in the region of the left ventricle. There was no fluid in the pleural cavity. The white-cell count rose to 26,000. No acid-fast bacilli were found in the sputum. No new abdominal symptoms or signs appeared, but he continued to complain of rather diffuse abdominal discomfort and distention. There was no peripheral edema. The temperature rose to 101 and later to 102.8°F on the succeeding two days. The heart action increased to 120, and increasing amounts of digitalis failed to control it. Mercury resulted in an output of 600 cc in twenty-four hours. A second x-ray film showed some clearing in the left upper lobe, but there was no definite increase in the right mid lung field and right lower lobe. A shadow in the right mid lung field had the appearance of consolidation, whereas all the remaining shadows were consistent with edema.

He failed to respond, continued in peripheral shock, a gallop rhythm appeared the respirations became shallow, the blood pressure dropped to 100 systolic, 80 diastolic, and the breath seemed slightly urinous. He quickly failed and died on the eleventh hospital day, three days after the onset of the terminal acute illness.

DIFFERENTIAL DIAGNOSIS

DR. PAUL D. WHITE "Three years before this first admission two teeth became infected and the joints of both ankles and knees became exquisitely tender to pressure and motion. All his

teeth were removed and a few weeks later his illness cleared, but complete recovery required six months." That sounds like past history, unless we assume that he was not well during that period, he may of course have had active rheumatism all through these three years. Thus it is a question whether this is the beginning of the present illness or whether it is past history. This sickness appears to have been rheumatic fever, probably his first rheumatic infection coming on at the age of thirty-five. Possibly it was rheumatoid arthritis, but in view of what is found later the more plausible interpretation is rheumatic fever.

There is no statement as to why his tonsils and adenoids were taken out. Evidently the tonsils were large and infected and were removed largely because of the presence of rheumatic heart disease.

Then we come to the first acute episode. He suddenly became dyspneic and exhausted. The physician who gave digitalis must have found something wrong with his heart. Dyspnea alone does not demand digitalis right away. It is likely that he developed tachycardia at the time he climbed three flights of stairs and that may have produced the dyspnea, tachycardia is produced in that way very frequently in a person with rheumatic heart disease. It was probably the onset of auricular fibrillation with rapid rate induced by effort. However, that is simply speculation at the moment. The dyspnea apparently subsided and he went to bed and fell asleep. Then came the severe, knifelike pain in the epigastrium which at first remained in that position and then shifted in a way absolutely characteristic of renal and ureteral colic because of the distribution of the pain to the right groin and testicle. Subsequent attacks occurred and each subsided quite quickly. The history does not reveal his state of health between the attacks. We may assume it was quite good and that these were isolated attacks—at intervals of three weeks first, and then of six weeks. The attacks were like renal colic, which is usually due to stones or gravel, but may possibly be ascribed to infarction from embolism.

The question that intrigues me most is the possibility of embolism producing such characteristic renal colic. I have not heard of its doing so, that is embolism to the kidney secondary to the occurrence of auricular fibrillation in the presence of heart disease and intracardiac thrombosis. It is very uncommon for the discomfort in such cases to radiate as far as the right testicle. However, we must entertain the possibility.

He was dyspneic at the time of the third attack, as he was just prior to the first attack of pain. Dyspnea may have accompanied each attack and

may even have been present between attacks.

There was no statement of clubbing of the fingers.

The findings on physical examination suggest that the heart disease was of long standing. The left side of the thorax was prominent and probably had been since childhood, though there is no proof of it. We frequently see precordial thoracic bulging in the children's clinic in youngsters with big hearts due to congenital defects or to rheumatism developing in early life. There was definite cardiac enlargement. The heart may be pushed over, but if it were simply displaced the apex would be high in position and not so low as here.

We wonder whether the heart rate had been rapid right along or whether the tachycardia came only with these attacks. It is unusual to have presystolic murmurs in the presence of auricular fibrillation. The murmur may have been only mid-diastolic, or we might question its presence altogether. On the basis of these findings we have probable confirmation of the diagnosis of rheumatic heart disease with mitral stenosis, auricular fibrillation and pulmonary congestion, not necessarily due to failure but rather to the tachycardia. The heart rate was so rapid that adequate auscultation could not be carried out at that time.

Apparently there was no abdominal (or flank) tenderness, which would help to rule out a surgical abdominal emergency in this case, since he was quite alert at the time of the examination.

This man had moderate fever. It is not our experience that fever, even as little as this, is produced by congestive failure alone. There is almost always some other factor, an active infection somewhere, or infarction. There might conceivably be renal or ureteral infection due to stone, or renal infarction, or recurrent active rheumatism in a man who has had previous attacks, any of these conditions, especially active rheumatism, may precipitate auricular fibrillation, as well as cause fever.

The white-cell count was higher than we would expect from anything but moderately severe infection, or marked infarction, it was distinctly higher than we usually find with myocardial infarction or with small pulmonary infarcts.

The red and white blood cells in the urine are probably not to be explained by congestion alone. They are in keeping with renal stone or other renal disease, including infarction.

The patient was digitalized, though it was stated that he did not respond in the usual way to digitalis doses in that the ventricular rate was difficult to control. It is common to have difficulty in

controlling the ventricular rate in congestive failure in the presence of infection or infarction. A third cause for such difficulty is thyrotoxicosis of which there is no evidence here. He probably had spontaneous recovery from this acute episode. Then, I judge, the heart rate came down, because there is only a slight pulse deficit recorded there after. The symptoms cleared, but doubtless he still had the auricular fibrillation.

Were there any x rays of the chest, kidneys, or ureters taken at the time? Is that a permissible question for me to ask?

DR. HOWARD B. SPRAGUE: There were no x rays taken at that time.

DR. WHITE: Any blood cultures?

DR. SPRAGUE: No. His apex rate was 75 at discharge, and the temperature was normal.

DR. WHITE: Was the pulse still irregular at discharge?

DR. SPRAGUE: Yes.

DR. WHITE: He did well apparently after this illness. There is no note of anything more until six months before his re-entry to the hospital which in a chronic rheumatic heart patient might mean that the chronic auricular fibrillation was well controlled.

Was he continued on digitalis over that period of time?

DR. SPRAGUE: Yes.

DR. WHITE: Had the presystolic murmur become mid-diastolic at this time?

DR. SPRAGUE: It was a definite diastolic murmur at the apex.

DR. WHITE: The soft blowing diastolic murmur at the left sternal border would make one think of the probability of aortic regurgitation as an additional valve lesion.

DR. SPRAGUE: That murmur was first noted in December, 1935.

DR. WHITE: What is the time relation of that to this report?

DR. SPRAGUE: The second admission was in April, 1936. Apparently it appeared between June 1935, and December, 1935, during which time he had gone through a period of severe carbuncles in his neck, and I noted the murmur at that time.

DR. WHITE: The heart examination would indicate the presence of mitral and aortic regurgitation, probably stenosis of both valves, though more of the mitral valve. There is one other possibility than that this aortic regurgitation had developed as a sequence to recurrent rheumatism, and that is, that syphilis may have come in, despite the earlier negative Hinton reaction resulting in both rheumatic and syphilitic valvular disease, although we do not often see that combination.

Were there new serological tests at the time, Hinton or Wassermann reactions?

DR. SPRAGUE: I think not. I do not think syphilis was a possibility.

DR. WHITE: I suspect it is not probable, but it has to be thought of.

Assuming that the technic was correct, the intravenous pyelogram showing no evidence of excretion of dye on either side, would mean that there was a good deal of kidney damage with inability to concentrate, a bad renal state, probably from many years of renal involvement.

"No friction rubs were heard. They were thinking of pleurisy due to pulmonary embolism and infarction."

"The blood pressure rose temporarily to 220 systolic, 80 diastolic." Very frequently the blood pressure in an acute episode goes up under the influence of pain or other exciting factor even including coronary thrombosis. I have seen it higher than normal in such cases before it settles back or finally becomes quite low, a low pressure is sometimes due to rest in bed for a long period of time rather than necessarily to a state of shock or heart failure.

In spite of the abrupt appearance of these signs in the lungs, there was no wheezing cough or hemoptysis, no pain, and no obvious air hunger or cervical vein engorgement." That statement does not rule out multiple pulmonary emboli. One can have embolism in the lung without any symptoms. One can have any kind of symptoms and very little in the way of signs.

Our patient had a barium enema, two chest x-ray examinations and an intravenous pyelogram. The barium enema showed nothing abnormal. A considerable portion of the terminal ileum was normal. Why was the barium enema done?

DR. SPRAGUE: The barium enema was done because the abdominal pain did not localize on one side, went from right to left, and in the past he had attacks of abdominal pain of a vague nature with some diarrhea relieved by belladonna, and the question arose as to whether he had a lesion of the large bowel.

DR. AUBREY O. HAMPTON: The first of these chest plates that we have is the best one and shows a grossly enlarged heart. Even though this is a portable film there is as much enlargement downward as to the left. This density in the lungs is almost exactly symmetrical, and it does end rather abruptly at the middle of the lung field. The right lower lobe is more radiant than the left chiefly because the heart shadow is large on that side. He has one line at the dome of the diaphragm that was not described. It could be an

old scar from infarction or infection. In the films taken the following day I think you can see a fairly definite change in the chest. The left upper lobe and even perhaps the right upper lobe look clearer than before. The right lower lobe now presents the same density as the remainder of the abnormal portion of the lung. This shadow of the right border of the heart was the one assumed to be something different from the remaining shadows, but it could be dilated blood vessels superimposed upon the same general condition. It is not sharp in outline and has no really characteristic shape.

DR. WHITE: May I ask if in cases of large heart it is conceivable that there may be some unusual pressure in the lower pulmonary vessels to limit the entrance of emboli? Has it been the finding that in rare cases emboli may go only to the apices?

DR. HAMPTON: I do not think we have seen pulmonary infarction produce this picture. We have seen this picture associated with small infarcts, but this lesion is almost wholly confined to the upper lobe and it certainly would be unusual for infarction.

The intravenous pyelogram is not satisfactory from the standpoint of viewing the kidney outlines, but I think that if dye had been excreted you would have been able to see it, particularly in the bladder. The bladder contains no dye after forty minutes. It contains urine. We can say that it is normal in size.

DR. WHITE: He evidently died in shock with failure of the kidneys, heart, and lungs, but not really a great deal of heart failure. I am very much intrigued, though I probably am wrong, by the appearance of the lungs in the x-ray picture and the prominent involvement of the upper lobes; infarction can happen but is less common certainly, according to the paper by Hampton and Castleman,¹ in the upper lobes and right middle lobe. Seventy-four per cent was their figure for the location of pulmonary infarcts in the lower lobes.

DR. HAMPTON: When we found infarcts in the upper lobes we almost invariably found them in the lower lobes also.

DR. WHITE: That is the most interesting and puzzling part of the whole case, the findings in the upper lobes; infarction alone would hardly seem likely. There has also been a change in the pictures, and one would think therefore that it has not been wholly a chronic state. Bronchopneumonia would hardly seem likely to involve both upper lobes in this way, nor would tumor. Tuberculosis might, but this is not the picture of tuberculosis.

Was there any electrocardiogram?

DR. SPRAGUE: Not in the hospital records. The others were not helpful.

DR. WHITE: The best I can do is to diagnose rheumatic heart disease, probably acute as well as chronic, probably recurrent, perhaps existing all this time in a mild degree. There are some cases of long-standing rheumatic involvement—ten years or more in adults. There was in this case rheumatic involvement of both aortic and mitral valves in all probability, with less likely syphilitic aortic involvement. The heart was undoubtedly big with auricular fibrillation, on the edge of failure, and yet with very little actual congestive failure that I can find. The involvement of the lungs I first labeled pulmonary infarction with edema and terminal infection, I am now wondering if a rheumatic involvement of the lungs could account for it, a rheumatic pneumonitis, but I am not familiar with its limitation to the upper lobes. Renal calculi should be found, or extensive renal infarction, but more probably calculi, with extensive damage to the kidneys. There may have been coronary thrombosis, subacute bacterial endocarditis, pericarditis, or disease of the aorta such as dissecting aneurysm, but the evidence does not support these diagnoses.

DR. J. H. MEANS: I should like to ask Dr. Sullivan if he recalls Dr. A. Thornton Scott's findings on the distribution of edema in the lungs in cases of Bright's disease.

I recall being very much surprised, a few days ago at our Medical Grand Rounds, when Dr. Schatzki showed a film with haziness in the middle portions and apices of both lung fields, but with perfectly clear bases, and said that it looked like edema. I had supposed that edema would be most marked at the bases and least marked at the apices.

DR. EUGENE SULLIVAN: I do not recall the exact figures, but there were some cases where the pulmonary edema was not at the base, but higher up.

DR. EDWARD F. BLAND: I went over the cases with Dr. Scott, and one or two showed predominant involvement in the upper lobes. The pictures were striking and cleared rather rapidly in some cases.

DR. MEANS: Something rather like this?

DR. BLAND: Surprisingly like this.

DR. HAMPTON: A similar picture occurs in heart disease alone. I remember one case we had here some time ago with a picture quite similar to this, and it proved to be rheumatic heart disease and nothing else.

DR. SULLIVAN: One case was verified at autopsy with edema in the upper lung fields.

DR. T. DUCKETT JONES: I think what Dr. White

said about long standing rheumatic fever and in creasing heart failure for years is obvious, but how this terminal feature could be associated is difficult for me to understand. The picture and clinical story are not that of rheumatic pneumonitis. Even as vague as the syndrome is, the patient with rheumatic pneumonitis is seriously ill before symptoms appear. The majority of them would have changes detectable by x ray study and would have changes in the lower lobes. I should say it seems unlikely that it is a straight pneumonitis.

Dr. WHITE: The renal condition could be the last straw.

Dr. JONES: It would have to tie up with this. You have to have something comparable to block- ing off of the renal artery to explain the picture. I wonder if we could not mention a second diag- nosis of rheumatic heart disease and hyperneph- roma which would produce pulmonary metastases.

CLINICAL DIAGNOSES

Chronic rheumatic heart disease
Mitral stenosis and regurgitation
Aortic regurgitation
Congestive failure.
Auricular fibrillation
Pulmonary edema.
Acute rheumatic fever and pneumonitis?
Nephritis (? cause)
Uremia.

Dr. WHITE'S DIAGNOSES

Rheumatic heart disease, acute and chronic.
Mitral and aortic stenosis and regurgitation
Marked cardiac enlargement.
Auricular fibrillation
Congestive failure.
Pulmonary infarction, infection or edema (or combination thereof)
Renal and ureteral calculi or renal infarction.

ANATOMICAL DIAGNOSES

Rheumatic heart disease, acute and chronic, with mitral and aortic stenosis.
Endocarditis, acute rheumatic, mitral and aortic valves.
Pericarditis, acute
Mural thrombus, left auricular appendage
Thrombosis of lower abdominal aorta with oc- clusion of common iliac vessels, lower aorta, left renal artery and superior mesenteric artery, acute.
Infarction of left kidney, acute.
Infarction of small bowel early
Pulmonary congestion and edema both upper lobes.
Rheumatic pneumonitis?

Cardiac hypertrophy, involving the right ven- tricle and left auricle.

Hydrothorax, bilateral, slight.

Chronic passive congestion of liver and spleen

Renal infarcts, healed, bilateral.

Cholelithiasis.

PATHOLOGICAL DISCUSSION

Dr. TRACY B. MALLORY: The underlying process, of course, was rheumatic heart disease. There was a greatly enlarged heart, 650 gm., and there was involvement of both mitral and aortic valves. There was a marked degree of stenosis in the mitral valve, a significant degree of stenosis and also regurgitation in the aortic. A few small fresh rheumatic vegetations were present and there was also an acute pericarditis. The coronary ar- teries were negative. The hypertrophy was pres- ent on both sides of the heart but more marked on the left. The lungs were rather large, very heavy, obviously edematous. On gross examina- tion slight but poorly outlined areas of consoli- dation seemed palpable in the upper lobes. On microscopic examination there was no very con- vincting pneumonia. There was a somewhat patchy edema, quite a little atelectasis, occasional al- veoli containing some fibrin and a few fibro- blasts attempting to organize it, but no leuko- cytic infiltration. There were no fibrous plugs in the bronchi or the respiratory bronchioles such as Masson, Ruopelle and Martin² have described in rheumatic cases, and no very extensive lobular alveolar hemorrhage such as we have seen in acute rheumatic cases. I certainly could not re- cognize it as rheumatic pneumonia and I doubt if it is, but I am too vague as to what the lesion is in that condition to be dogmatic. The ter- minal event unquestionably was a series of emboli. The main branch of the left renal artery was plugged by a fresh embolus, and small fresh emboli were found in the small branches of the right kidney. There also were scars of old in- farction in both kidneys. The renal embolism must have gone back many years, and I think, in retrospect, accounts for the early attacks of pain with radiation to the testicle.

Dr. WHITE: Were there any stones?

Dr. MALLORY: No. There were two more im- portant emboli which probably precipitated death. One was to the superior mesenteric artery which was completely plugged, although the bowel had not become gangrenous. The other was a rider embolus of the aorta blocking both iliac arteries.

Dr. WHITE: I called up a urologist to inquire whether typical renal colic with radiation to the testicle could be caused by renal infarction and he said he did not think so.

DR MALLORY Either you did not call the right urologist or his memory is short, because in this hospital they have explored patients for renal calculi and found infarction

A PHYSICIAN Were there any renal emboli and infarcts?

DR MALLORY There were a few

CASE 26232

PRESENTATION OF CASE

A fifty-six-year-old Japanese cook was admitted to the hospital complaining of dyspnea on exertion

The patient had always been in robust health and had taken pride in his physical prowess as a wrestler and swimmer. He was thus active athletically until approximately two years before admission, when he began to tire easily. For several months before entry he noticed gradually progressing dyspnea on exertion. One month before admission he had had a bad cold, and an examination at that time by his physician revealed that his blood pressure was 130 systolic. The cold improved slowly and he seemed fairly well until the evening before entry when, immediately after supper, he experienced the sudden onset of dyspnea (without exertion), substernal oppression, but no pain or other discomfort anywhere. He opened a nearby door in an attempt to obtain more air, took soda and salt water without relief, coughed slightly, and raised moderate amounts of white frothy sputum. A physician who was called found the patient coughing and wheezing. He appeared ill and had a blood pressure of 156 systolic, 70 diastolic. He denied ever having had asthma or a similar attack before. A quarter grain of morphine sulfate was administered hypodermically, and the patient slept the night through, sitting erect. At 6 a m on the morning of admission he was again seen by his doctor and was found to be wheezing, with a blood pressure of 106 systolic, 60 diastolic. Examination of the heart at that time was not remarkable. Because of his symptoms he was referred to the hospital for treatment.

The family and past histories were, so far as was known, negative.

Physical examination showed a remarkably well-developed, well-nourished, muscular man who was orthopneic, dyspneic and cyanotic, with "asth-

matic" wheezing respirations. He could lie flat but was uncomfortable in so doing. There were rhonchi and wheezing throughout the chest, with rales at the bases posteriorly. The vital capacity was definitely limited. The heart was slightly enlarged to percussion. The heart sounds were not well heard because of the other sounds, although they seemed to be of poor quality. A split second sound, but no murmurs, was heard over the precordium, there were no murmurs. There was no edema or ascites. The liver and spleen were not palpable. The blood pressure, which was 128 systolic, 65 diastolic, in the sitting posture, was 160 systolic, 80 diastolic in the supine position.

The temperature was 101°F, the pulse 130, and the respirations 44.

Examination of the blood showed a red-cell count of 7,500,000 with 95 per cent hemoglobin, and a white-cell count of 13,000 with 92 per cent polymorphonuclears, the smear was normal. No urine was obtained for examination. The blood Hinton test was positive, the Wassermann weakly positive. An electrocardiogram showed a normal rhythm at 105, with a PR interval of 0.18 sec, and left bundle branch block. The corrected sedimentation rate was 0.4 mm per min, and the hematocrit reading 48 per cent.

The patient was given 10 cc of aminophyllin intravenously, and seemed quite well and comfortable during the day of admission, with but few wheezes at both lung bases. At 1.00 a m the night after admission, he became mildly dyspneic. Oxygen was administered by the nurse, and the dyspnea soon cleared. At about 2.30 a m, however, he suddenly became rapidly dyspneic and cyanotic, did not complain of pain, but attempted to remove the oxygen mask. In so doing he fell back dead.

DIFFERENTIAL DIAGNOSIS

DR MYLES P BAKER It would seem to me that the burden of proof in this case lies with the man who declares this is not a case of acute coronary occlusion on the basis of sclerosis of the coronary arteries. The man's age, fifty-six, is in the decade in which clinical coronary thrombosis is most frequently observed. There have been several months of progressive exertional dyspnea without anemia, of progressive exertional dyspnea without increased metabolic rate or respiratory-tract obstruction to account for the dyspnea. This is presumably cardiac dyspnea with diminishing cardiac reserve, the earliest symptom of a failing left ventricle, with pulmonary vascular congestion. The respiratory tract infection with cough is an added strain on the heart muscle. The paroxys-

mal dyspnea with substernal oppression was the most prominent symptom, more so than any crushing pain. It is the picture of cardiac asthma, of acute left ventricular failure, this is well known to be the conspicuous feature in some cases of proved coronary occlusion and myocardial infarction. Asthmatic rales were prominent, and interfered more, I gather, than the simple basal rales of congestive failure, with ascertaining whether the heart sounds were of good quality. It is important that no early diastolic blowing murmur of aortic regurgitation was audible. The blood pressure fell over night. The next day the patient presented a picture of left-sided ventricular strain and failure with little evidence of right-sided failure. The blood-pressure reading which showed a lessened pulse pressure when he sat up, I take to be simply evidence of lessened ability of the circulatory apparatus to adapt to the change in position. This finding is observed in some hypertensive patients but I think in this case is an indication of handicap in the circulatory apparatus. We have no evidence here for stating that the man had an antecedent hypertension. They have taken particular pains to tell us that during the acute episode the blood pressure was normal.

The fever on the day following the onset of symptoms, the rapid heart rate and the leukocytosis are all consistent with a diagnosis of myocardial infarction. The white-cell count is rather high, to be sure. The heart sounds were somewhat indistinct, in keeping with such a diagnosis. One wonders whether one could distinguish between a split second sound and gallop rhythm at the rate of 130. The electrocardiographic evidence of left bundle-branch block is consistent with the diagnosis of coronary occlusion. I believe this abnormal tracing sometimes occurs after an acute occlusion. On the other hand, it may indicate impoverishment of the blood supply of the heart muscle dating back over the months of exertional dyspnea, and the basis for such a process would be arteriosclerosis of the coronary arteries. The sedimentation rate I am inclined to discount as equivocal. The high red-cell count represents, I take it, a relative polycythemia due to the state of anoxemia, rather than being indicative of a true polycythemia.

Two questions arise as to differential diagnosis: the first as to whether this sudden accident and subsequent heart failure could be related to disease of the aorta. I think we can dismiss the possibility of a dissecting aneurysm because of the absence of outstanding pain with reference to the back and legs and the lack of a persisting hyper-

tension. The question of a pulmonary embolus with acute cor pulmonale arises. I think the absence of any previous accident to the legs, however slight, the absence of edema of an ankle or any story of phlebitis and the absence of the characteristic evidence, however transient, which may by electrocardiogram be demonstrated after acute pulmonary emboli, are all points that would make us unable to ascertain that diagnosis, however, it should be thought of—I think probably it was—in a man whose complaint was dyspnea and sternal oppression rather than pain.

Did syphilis play a part in this man's demise? He may well have had latent syphilitic aortitis, for such is not uncommonly the case, and perhaps one out of five individuals with latent syphilitic aortitis has no symptoms that would lead one to suspect the diagnosis. But I think two points are important: the paroxysmal dyspnea such as this man had is strikingly absent in uncomplicated syphilitic aortitis, and, although perhaps one out of six cases of syphilitic aortitis may have involvement of the coronary orifices in the process in the wall of the aorta, only about three fifths of these have symptoms of coronary insufficiency. I think it most unlikely then that even if this man did have syphilitic aortitis, for which there was no time to be more certain by a ray examination, his symptoms were due primarily to it, but rather to coronary disease with which the syphilis of the aorta was merely associated if present at all. Myocardial infarction as a result of a syphilitic process that partially or completely blocks the orifices of a coronary artery is rare indeed, and among cases reported from the Presbyterian Hospital there were only three or four of this sort noted.¹

The rare causes of relatively sudden cardiac death in cases with syphilis are probably not present here. Acute syphilitic myocarditis has been described but is still a point of controversy, and in such cases as I could find reported from the Baltimore City Hospital² about five years ago all were in younger individuals dying much more suddenly than this man who lived thirty-six hours after the first attack.

I should conclude that this man had, and that the pathologists would find, coronary thrombosis with myocardial infarction and possibly a syphilitic process at the root of the aorta, which one was unable to be more certain about during life.

DR. J. H. MEANS: The first attack that he had sounds like a textbook description of acute pulmonary edema which might have been an occurrence not necessarily associated with coronary disease. I agree that the argument in favor of coronary oc-

clusion is very convincing I should just like to mention that Dr Mallory did an autopsy for me some years ago on a patient whose manner of exitus was very similar to that of this man, so far as I can judge it from the description just given, and found no thrombosis of the coronary arteries, no infarction, nothing but a narrow coronary, narrowed by an atheromatous process. So I just throw that out as a possibility in this man, not as a probability.

DR TRACY B MALLORY Drs Blumgart, Schlesinger and Davis,³ as many of you undoubtedly know, have recently published a paper concerning the clinicopathological correlation of coronary artery disease and infarction of the myocardium in a considerable number of cases. They make a point with which I am very much in sympathy, namely, that the clinical diagnosis of coronary thrombosis is made very casually without realization that the syndrome is really that of infarction of the heart. Pure coronary thrombosis very frequently produces no recognizable clinical symptoms, and a diagnosis of coronary thrombosis does not necessarily connote infarction of the heart and vice versa. Dr Baker has committed himself to both coronary thrombosis and myocardial infarction.

DR PAUL D WHITE I want to make a correction in the electrocardiographic interpretation. It should read right bundle-branch block rather than left. That brings up the possibility, as in a case discussed here a while ago, of widening of the QRS complex of the right bundle-branch type as due to cor pulmonale, a very unusual but interesting association. It is therefore conceivable, though not likely, that this patient had recurrent pulmonary infarction rather than massive myocardial change from coronary disease.

DR MEANS If that is the case, pulmonary artery thrombosis becomes a possibility.

CLINICAL DIAGNOSES

Coronary heart disease
Paroxysmal nocturnal dyspnea

DR BAKER'S DIAGNOSES

Coronary thrombosis
Myocardial infarction
Syphilis of aorta?

ANATOMICAL DIAGNOSES

Coronary sclerosis, severe
Myocardial infarction, left ventricle

Syphilitic aortitis with aneurysm
Pulmonary edema and congestion

PATHOLOGICAL DISCUSSION

DR MALLORY The autopsy showed an enlarged heart, weighing 450 gm. There was massive infarction of almost the entire left ventricle, including the major part of the interventricular septum. The coronary arteries showed no demonstrable occlusion. They were everywhere markedly narrowed by atherosclerotic processes, and their mouths, particularly the mouth of the right coronary artery, were markedly narrowed by scars in the base of the aorta just above the aortic valve, which were undoubtedly syphilitic in origin. There was a very slight degree of separation of two of the aortic cusps. The conviction that this was a syphilitic process was raised to certainty when we found a small aneurysm at the beginning of the arch and a microscopic appearance entirely characteristic of syphilitic aortitis.

The lungs showed a very marked grade of pulmonary edema, and the other organs a slight amount of passive congestion, nothing else. So far as the autopsy was concerned I think we have good evidence of left-sided heart failure, and practically no evidence of right-sided failure.

DR MEANS Since this man was Japanese, since we know diseases of this type vary from race to race,—we know, for instance, there is a difference between Negroes and Whites,—and since Dr Cadbury, who is with us this morning, has just come back from Canton, I should like to ask him about coronary thrombosis and so forth in the Japanese. The Japanese now occupy Canton. Do they differ from our race with regard to cardiac symptomatology?

DR WILLIAM W CADBURY I cannot speak for the Japanese. I see none of them. We send them to their own hospital. In the Chinese, coronary thrombosis is extremely rare.

DR MALLORY How about cardiovascular syphilis?

DR CADBURY That is present. We get a fair amount of syphilitic disease of the aorta. Hypertension is relatively rare among the Chinese race.

THE ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

For one hundred and fifty-nine years this oldest medical society, with a continuous existence in the United States, has conducted its annual sessions. The meeting this year was at the Copley Plaza Hotel, Boston, May 21 and 22.

Every detail of the program, arranged by the committee in charge, was ready for the assemblage. After registration and study of the agenda, the fellows and guests devoted time to the scientific sessions, inspection of the scientific and commercial exhibits and conferences.

The total registration for the two days was 1461, but some of those present did not have their names recorded.

The round-table meetings and luncheons, arranged for the noon intermission of the main

program on the first day, enabled the specialists to meet and discuss their particular problems with out adjustment to the needs of a general audience. By this arrangement all fellows, except the coun- cils, could attend any scientific session without missing any subject on the program.

The attendance at the several meetings of the specialists was 89 for medicine, 70 for pediatrics, 144 for obstetrics, 50 for surgery and 50 for der- matology.

Twenty-two members competed for the award of the Burrage Bowl and other prizes, the winners being Oliver Lothrop, low net, J. W. Henderson, 2nd low net, Thomas Cavanaugh, 3rd low net, R. S. Nugent, low gross, Robert Dutton, 2nd low gross and Joel Melick, 3rd low gross.

Provision was made for the visiting ladies to play golf, sign up for treks to various places of interest and for dinner at Horticultural Hall fol- lowed by a Pop Concert. About two hundred visiting ladies registered, but the number participat- ing in the special features of the program for them is not available.

Two hundred and twenty-eight attended the Tuesday morning general clinical meeting. The Council meeting was in session at the same time, thereby affecting attendance. In the afternoon the number rose to 388, and, with the increased regis- tration on Wednesday, the attendance at the morn- ing clinical meeting was brought to over 400. In the afternoon the number reached at least 600, for many could not get into the hall. The attend- ance at the annual dinner on Tuesday evening was 264. The quality of this repast was unusually good and the social atmosphere was enjoyable.

The address of Thomas Parran, Surgeon Gen- eral of the United States Public Health Service, in his delineation of the serious situation confront- ing the world and imposing great responsibilities on the people of this country, was a stirring ap- peal for united support of all classes. When, in closing, he portrayed the part medicine must play not only in meeting the peril to the health of the country but beyond that because of its under- standing of the psychology of all classes and its opportunity for assuming leadership in maintain- ing the traditions and ideals of the preceding

years, he roused his audience to an outburst of applause which demonstrated his power to bring his hearers into harmony with his convictions

The audience then adjourned to attend the Shattuck Lecture¹ in the adjacent hall, where 575 met to hear Dr Ernest W Goodpasture present a record of the efforts under way and the facts acquired in studies of the problems involved in virus infections and immunity relating thereto His treatment of the complicated and abstruse subject of virus diseases was a demonstration of his ability to interest the average doctor and make clear the methods of approach to these problems

A very large proportion of the 320 councilors were present at the meeting of that body, held on the forenoon of the first day This is a demonstration of the interest shown by these officials in the affairs of the Society

The first business on the program was the calling of the roll of the Nominating Committee with responses from delegates representing all but one of the eighteen district societies The committee retired and soon returned, reporting a list of names for consideration of the Council, as follows for president, Walter G Phippen, of Salem, vice-president, Frank R Ober, of Boston, secretary, Alexander S Begg, of West Roxbury, treasurer, Charles S Butler, of Boston, and orator, A Warren Stearns, of Billerica No other nominations appearing, the recommendations of the committee were approved and the Council unanimously elected the persons named for the respective offices

Most of the time was given to consideration of the reports of the standing and other committees So much study had been given to the duties of these committees and so much care in the drafting of their reports that they were accepted and the several recommendations adopted with only minor amendments in few instances and with no extended discussion

The President's nomination for membership of committees was submitted and adopted without debate No incidental business having been proposed, the meeting was dissolved after being in session less than an hour and a half, it was gen-

erally regarded as one of the shortest Council meetings of many years The official record will be published in the June 20 issue of the *Journal* and should be studied by the fellows of the Society for, according to certain recommendations: changes in the by-laws, as suggested by the Committee on Medical Education and Medical Diplomas, should have study by the general membership

The annual business meeting of the Society, with the President's address and the Annual Discourse was called to order by the President at eleven o'clock Wednesday morning The first business was the report of the Secretary, showing that the losses to the membership consisted of 99 deaths, 23 resignations and 38 deprivations, making total of 160 The additions consisted of 252 new members with 3 readmissions and 10 restoration a total of 265, making a net gain of 105, bringing the membership to 5542

No item of business appearing, the President then delivered the annual report on the condition of the Society, which he described as "very healthy" and after paying tributes to the Secretary, Treasurer, the councilors, committee members and a who have assisted in the administration of the affairs of the organization, he appealed for a concerted effort to induce all worthy physicians of this State to become members of the Society

He then explained the methods adopted for conducting the affairs of the American Medical Association and the relation of this Society thereto Other subjects presented were the advisability of more general utilization of the clinical material of the many hospitals in the State for postgraduate education, careful financial planning of the activities of the Society, and maintenance of the traditions and high principles of the profession so that the pitfalls into which some societies have fallen may be avoided This address and other delivered at the meeting will be published in early issues of the *Journal*

The Annual Discourse by Dr William Jaso Mixter on "New England, Neurosurgery and the Neurosurgeon" was then delivered² This essay will take high rank among others delivered before the Society

The meeting then adjourned for luncheon, furnished by the Society, with 327 members participating.

The general arrangements for the meeting were frequently commended by those in attendance with approval of the work of the Committee of Arrangements and the hope that subsequent meetings will follow the general scheme of this year. The only dissatisfaction expressed was that for a society of this size and with a very attractive program for its annual meeting, the attendance seemed to indicate that the large number of absentees do not appreciate the advantages of attending these meetings. However that may be, it is certain that those who were present profited by the experience.

TWENTY FIRST ANNUAL REPORT OF THE COMMONWEALTH FUND

On October 17, 1918, the Commonwealth Fund was established by Mrs. Stephen Harkness with the avowed purpose of applying the resources of this trust to "promote the welfare of mankind." Every year since that time a report giving the details of the activities carried on by the administrative staff and the five main divisions, including the committees appointed for specified functions and the Child Guidance Council of Great Britain, has been published. These documents have demonstrated a broad conception of methods that may be employed to meet the problems relating to medicine, public health, and economic and sociologic conditions of the human race. It is probably true that the inciting reason for the establishment of this fund in 1918 was the chaotic situation incident to the war at that time, and although for several years grants from the fund were provided to help in the rehabilitation of the social structure, as time went on its interests became especially concentrated in the promotion of American health and agencies connected with

progress in this direction. These yearly reports show the accomplishments of this organization and demonstrate the wisdom of the plans adopted and the executive ability exercised in their application.

During the twenty-one years of operation nearly \$24,000,000 have been distributed to hospitals, state health departments, medical schools, clinics and medical societies. One interesting movement has been that of financing studies relating to criminology and various forms of social service, apparently in furtherance of the plan to bring preventive measures to bear on delinquency, which is possibly a factor in establishing anti-social tendencies.

Fortunately the educational features of this report are not obscured by dry statistical tables, but are presented in an engaging fashion which carries assurance of the generous concern of the officials of the Commonwealth Fund in the problems of human welfare. The report is worthy of careful study because of its informative quality, it will interest every student of the problems of medical education and public-health administration.

MEDICAL EPONYM

BUERGER'S DISEASE

Leo Buerger's (1879-) description of the disease bearing his name first appeared in the *American Journal of the Medical Sciences* (N. S. 136:567-580, 1908), under the title "Thrombo-angitis Obliterans. A study of the vascular lesions leading to presenile spontaneous gangrene."

The disease occurs frequently although not exclusively among the Polish and Russian Jews. We usually find it occurring in young adults. After longer or shorter periods, characterized by pain, coldness of the feet, ischemia, intermittent claudication and erythromelalgic symptoms, evidences of trophic disturbances appear which finally pass over into a condition of dry gangrene. I have come to the conclusion that we are dealing here with a thrombotic process in the arteries and veins followed by organization and canalization and not with an obliterating endarteritis. I would suggest that the names "endarteritis obliterans" and "arteriosclerotic gangrene" be discarded in this connection, and that we adopt the terms "obliterating thrombo-angitis" of the lower extremities when we wish to speak of the disease under discussion.

PYELITIS OF PREGNANCY TREATED BY NEPHROSTOMY

Mrs. E. L. F., a twenty-five-year-old primipara, five and a half months' pregnant, was admitted to the hospital on February 19, 1932, complaining of pain in the right groin with chills and fever of five days' duration. Shortly before there had been a milder attack with pain on the left side.

The family history was irrelevant. She had had no miscarriages and no children. An appendectomy had been performed four years previously. Catamenia had always been regular with a twenty-eight-day cycle and lasted three to four days without dysmenorrhea. The last regular period had occurred on September 17, 1931, making the expected date of confinement June 24.

Physical examination revealed a well-developed and fairly well-nourished young woman who presented the appearance of serious illness. The temperature on the evening of admission was 99.4°F, the pulse 124, and the respirations 28. The following morning the temperature was 102°F, the pulse 120, the respirations 24, and the blood pressure 95 systolic, 65 diastolic. The fundus of the uterus was at the level of the umbilicus. There was slight tenderness but no spasm in the right lower quadrant. Extreme tenderness and some muscle resistance were found in the right lumbar region. The entire abdomen was markedly distended, and the flanks were faintly edematous. A catheter specimen of urine contained innumerable pus cells in large clumps. The white-cell count was 9800. On the day after entry the patient developed a generalized punctate rash, which a medical consultant believed to be the result of toxemia.

On February 23, four days after admission, and when an intensive medical program had failed to afford relief, cystoscopic examination was carried out. The pelvis of the right kidney was irrigated with boric acid solution, followed by the introduction of 10 cc of 2 per cent Mercurochrome. The catheter was left in position in the right ureter for twenty-four hours. The white-cell count at

this time was 22,000. The blood urea-nitrogen was 25.6 mg per 100 cc. The blood Wassermann was negative. Urine obtained from the right kidney was thick and purulent, and the sediment contained 30 or 40 pus cells per high power field, the culture showed colon bacilli.

Three days later, on February 26, the temperature was subnormal and the pulse 120. The patient seemed somewhat improved, but the right kidney was still large and tender. Antiseptic lavage of the right renal pelvis was repeated, and a ureteral catheter again left in situ. The urine from this kidney appeared to be less cloudy but still contained abundant pus. Two days later the temperature and pulse rate had begun to subside but abdominal distention persisted. There was a mass in the right lumbar region which seemed to be increasing in size, and the patient was definitely jaundiced. It was decided to do a right nephrostomy.

The operation was performed on March 1 under nitrous oxide, oxygen and ether anesthesia, with the evacuation of a large amount of thick pus from the renal pelvis. Convalescence from the operation was perfectly satisfactory, except that the blood showed a hemoglobin of 55 per cent, a red-cell count of 3,850,000 and a white-cell count of 18,000. Because of this, 400 cc of citrated blood was given by transfusion on March 8. The patient suffered an attack of mastoiditis two days later, which was treated conservatively. On April 1 perirectal abscesses developed, these were satisfactorily treated by poultices.

On April 16 the patient was delivered by low forceps of a premature child, who was in good condition. The patient was discharged on May 2. There is no follow-up record on this patient.

Comment. This is a most unusual and severe case of pyelitis during pregnancy, complicated by mastoiditis. Conservative medical treatment, renal lavage and ureteral catheterization failing, nephrostomy was performed with highly satisfactory results. This procedure is rarely necessary, and then only as a life-saving measure.

DEATHS

BENNER—BURNHAM R. BENNER, M.D., of Lowell, died May 29. He was in his ninety-fourth year.

Born in Pittston, Maine, he received his education in the public schools of Roxbury and the Harvard Medical School, receiving his degree from Columbia University College of Physicians and Surgeons, New York City, in 1875.

Dr. Benner was a member of the Massachusetts Medical Society and the American Medical Association, and had retired from active practice.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

GOODMAN—**SAMUEL GOODMAN** M.D. of Boston died May 28. He was in his seventy sixth year.

Born in Kalwarya, Lithuania he came to New York City in 1871. He received his degree from New York University Medical College in 1889 and began the practice of medicine in Boston the following year. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son and a daughter survive him.

SEARS—**GEORGE G SEARS** M.D. of Boston died May 27. He was in his eighty second year.

Dr Sears attended Amherst College and received his degree from the Harvard Medical School in 1885. He was former chief of the medical staff and trustee of the Boston City Hospital and was instrumental in founding the Thorndike Memorial Laboratory at the Boston City Hospital. Since 1924 he was a trustee of the Forryth Dental Infirmary and was professor emeritus of clinical medicine at Harvard Medical School.

Dr Sears was a member of the Massachusetts Medical Society, the American Medical Association and the Association of American Physicians.

A daughter and two grandchildren survive him.

long a patient should be hospitalized for a given illness. We know that treatment is not a matter of statistics.

The solution to this problem is to reach the subscriber with an appeal for fair play and to educate him in the fact that his full benefits are available only if needed but that abuse of these benefits could result in a general loss to all subscribers.

To this end we earnestly request your support.

R. F. CAHALANE *Executive Director*

Boston

REPORTS OF MEETINGS

BOSTON ORTHOPEDIC CLUB

At a meeting of the Boston Orthopedic Club at the Boston Medical Library on February 12 Dr Bernard M. Jacobson spoke on "The Diagnosis of Multiple Myeloma," describing studies by himself and Drs. Alfred Krane, Edward A. Gall and James R. Lingley. The speaker briefly recounted the previous eras in the diagnosis of this disease: the first prior to 1898 when the appearance of one or more visible tumors was the only method available, and the second from 1898 to 1933 when the condition was suspected only on roentgenological findings.

That multiple myeloma is actually increasing was demonstrated both by the percentage of admissions and by that of autopsies for successive periods. From 1913 to 1917 there were at the Massachusetts General Hospital 0.3 cases per 10,000 admissions and this increased to 3.5 cases from 1933 to 1937. That better diagnosis did not account for this rise was shown by the post-mortem statistics, which showed that there have been 6 cases of multiple myeloma in every 1000 autopsies since 1933 as compared with 1 case prior to that date. No cases have been solicited. Dr Jacobson pointed out. The modern era in the diagnosis of multiple myeloma which started at the Massachusetts General Hospital in 1933, includes 29 cases, which served as a basis for Dr Jacobson's talk.

The outstanding symptom was pain in 21 of the patients, in 9 of whom it simulated polyarthritis. Pain in the spine or hips, which is emphasized in textbooks, was found in only 8 and pleuritic pain predominated in 6 patients. Physical examination was not found very useful for only 11 of 28 showed abnormal signs. Five of these were in the spine, 4 in peripheral joints and 2 in the ribs.

It was in regard to laboratory data that Dr Jacobson found the greatest diagnostic assistance. Presumptive findings were Bence Jones proteinuria which occurred in half the cases, and plasma cells in the blood smear which were found in 20 per cent. Considered strongly suggestive evidence were "typical" roentgenological findings (40 per cent) a plasma protein value of more than 8 gm. per 100 cc. (50 per cent) and an elevated blood calcium in the presence of a normal phosphatase (40 per cent). Somewhat less suggestive tests were the characteristic precipitation of Hayem's solution (50 per cent) an anemia which tended to be macrocytic (90 per cent) and renal insufficiency (40 per cent).

The speaker then discussed each of these diagnostic aids in detail. The only diagnostic roentgenologic changes were described as small, fairly discrete areas of decreased density found most frequently diffusely distributed, in the skull (in 10 of 25 cases) pelvis (in 6 of 21 cases) spine (in 5 of 21 cases) and ribs (in 3 of 23 cases). This was found not to be a true index of the degree of bone marrow invasion, however for the last x ray films were

CORRESPONDENCE

A WARNING

To the Members of the Massachusetts Medical Society: A man giving the name of Roger Maloney and stating that he was engaged in the cancer education program called on a fellow of the Society April 16, at 9 p.m. claiming that he was stranded and needed a loan of three or four dollars. He gave my name as reference.

No one is employed by the Cancer Committee of the Massachusetts Medical Society or authorized to ask for funds.

SHELDON WARREN M.D., Chairman
Cancer Committee.

Boston.

ASSOCIATED HOSPITAL SERVICE

To the Members of the Massachusetts Medical Society: We have moved to larger quarters. Our new location is the Western Union Building, 230 Congress Street. Our telephone number is Hubbard 8800.

We appreciate the fact that the unusual growth of the Blue Cross, which made this move necessary within two and a half years is due largely to your acceptance and endorsement of our place in the hospital work of the community.

Three thousand two hundred and eighteen doctors have sent 38,000 Blue Cross patients to Massachusetts hospitals during the past two and a half years. With rare exception you have graciously co-operated with us in making fair decisions in connection with these admissions. Because we believe that 95 per cent of you are interested in the continued success of the Blue Cross we do not hesitate to lay before you one of our current problems.

We have observed the tendency of our subscribers to stay in the hospital as long as Blue Cross benefits are available. This indicates that the length of stay is very often governed by these benefits and not by the course of the patient's illness. We shall never attempt to decide here how

often negative even when the autopsy showed bone lesions. The differential diagnosis should include metastatic carcinoma, hyperparathyroidism, senile osteoporosis, Paget's disease and giant-cell tumor. It was suggested that if only one plate can be obtained that of the skull is most apt to be helpful.

Dr Jacobson stressed the importance of an elevated serum protein, which was found to depend on an increase of the globulin fraction. A total protein of more than 8 gm per 100 cc was found in 14 of 26 cases, while a globulin value above 3 gm. was present in all 13 patients in whom the determination was made. The formol-gel test, which depends on this latter phenomenon, was found positive in each of the 10 cases in which it was tried, and was advocated as the earliest and easiest means of determining the presence of this highly suggestive elevation of globulin. The precipitation of Hayem's solution during a routine blood count, which was noted in almost half the cases, was also attributed to this alteration in the blood.

Hypercalcemia of 11 to 14 mg per 100 cc. was observed in 9 of 22 patients, whereas the serum phosphatase had a value of less than 5 Bodansky units in 17 of these cases. This combination of circumstances, together with a serum phosphorus of 3 to 5 mg per 100 cc. found in 18 of 23 cases, helped in ruling out hyperparathyroidism, Paget's disease and most cases of metastatic carcinoma.

Renal insufficiency, evidenced by an elevated nonprotein nitrogen and a diminished phenolsulfonephthalein excretion in 13 of 29 patients, was considered to be caused by the amorphous precipitate found in the kidneys and identified as Bence Jones protein. The condition was described as a 'tubular hydronephrosis'. Terminal uremia ensued in 7 of 15 patients examined, and 10 of these exhibited pathological evidence of renal involvement.

Dr Jacobson pointed out that 24 of 29 patients were suspected of having multiple myeloma before biopsy or autopsy, as a result of following up an initial clue. This clue in 10 of 29 cases was offered by the roentgenograms either alone or together with a urinalysis or a renal function test. Anemia, usually with x-ray or blood chemical findings, showed the way in 6 cases, while altered blood chemical findings and the presence of plasma cells in the routine blood smear offered the initial clue in 4 or 5 cases each.

It was instructive that only 6 of 29 patients were saved because of symptoms—5 for back or hip pain and 1 for rib pain. Two cases were primarily considered to be due to pulmonary carcinoma and pleurisy respectively.

The diagnosis, Dr Jacobson pointed out, must be substantiated by histological examination. Biopsy sites suggested were accessible lesions, or cancellous marrow, such as that of the sternum studied by means of a sternal puncture. The latter established the diagnosis in 8 of 29 cases.

The prognosis was held to be grave. In 17 of the 20 fatal cases the patients died in one to sixteen months, with an average of seven months, while in 3 they lived two to three and a half years. One patient is living after five years, having had a peripheral lymph node positively diagnosed, but having as yet no demonstrable bone lesions by x-ray. Deep x-ray therapy, both local and spray, was found useless in prolonging life, and only of questionable value for the relief of spinal pain.

In discussion Dr George W. Holmes admitted that the skull offers the best single chance of finding bone lesions by x-ray but warned that lesions may occur elsewhere when the skull appears negative. He pointed out that roentgenological evidence is present only after involve-

ment of the cortex, which may occur late or never in a condition affecting primarily the marrow.

Dr Benjamin Castleman emphasized the importance of the technic of determining Bence Jones proteinuria. He said that solitary myeloma, although possible, is usually indicative of an early case or a single manifestation of an already widespread condition. Pathologically, splenomegaly was found in half the cases—a compensatory hematopoiesis for the decreased amount of bone marrow. The finding of a more or less normal phosphatase value was explained by the nature of the process, which is almost entirely destructive rather than formative.

Dr Jacobson concluded with the statement that the cancellous bone is invaded 100 per cent, despite negative x-ray evidence or gross autopsy examination. Patients with a "solitary plasmoma" have lived eight to ten years, but their span is usually two to three years, postmortem examinations reveal widespread disease and even early sternal biopsy is usually positive.

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on February 27, with Dr Frank R. Ober presiding.

There was the usual presentation of cases. The medical patient was a twenty-three-year-old girl admitted with a complaint of external dyspnea for one year and a chronic cough for six months. As a child, she had been admitted to the Children's Hospital complaining of nausea, vomiting, and stiff neck. The spinal fluid contained 5 monocytes per cubic millimeter, there was an anemia and clumps of leukocytes were found in the urine. She was discharged well but returned in two months with a positive Kernig sign, increased spinal fluid pressure and an elevated globulin content. A diagnosis of acute anterior poliomyelitis was made, and corrective operations were performed later. There were always clumps of white blood cells in the urine at subsequent admissions. The patient, being able to get around on crutches, had worked until one week prior to the present admission. Digitalis had been recommended six months before by a local doctor but was voluntarily discontinued in October. Physical examination revealed an enlarged heart with a pre-systolic gallop rhythm, basal rales in the lungs, weakness of the arms and a deformed left leg. The hemoglobin was 24 per cent, the erythrocyte count 1,400,000, and the leukocytes 6000. The serum calcium was 8.8 mg and the phosphorus 11.0 mg per 100 cc, and there was a reversed albumin globulin ratio. Roentgenograms demonstrated an enlarged heart, congestive lung changes, marked atrophy of the left leg and odd changes of the vertebrae. A blood transfusion was administered after an attempt to improve the patient's general condition, but there resulted temporary orthopnea. While in the hospital there was an episode of eight convulsions which finally responded to chloroform after intravenous calcium lactate and the barbiturates had failed.

Dr M. C. Sosman stated that the appearance of dense vertebral plates was disturbing when one was looking for evidences of renal rickets. In that condition one expects true decalcification rather than ossification. Dr Sosman Weiss remarked that the congestive failure was undoubtedly secondary to a chronic pyelonephritis dating from childhood although unsupported by a positive history. He noted the presence of left-sided heart failure, as evidenced by the x-ray films and by clinical manifestations, and the absence of right-sided failure, a combination which caused orthopnea only after a transfusion, and said that anemia

might explain this phenomenon. Dr Weiss added that bone changes are a common accompaniment of pyelonephritis occurring in childhood and may cause physical retardation and renal dwarfism.

The surgical case was that of a fourteen-year-old boy who was one of twins born at a difficult birth and who had had an illness at two years of age which was possibly poliomyelitis. Following that episode there was gradual difficulty in touching his left heel to the ground. Athetosis of the left arm developed at the age of nine, and a chordee only for postencephalitic athetosis was performed three years later at another hospital. Somewhat later there intervened episodes of falling backward his head was held to the right with hypertrophy of the neck muscles, and there was weakness of the muscles on the left with spasticity of the leg on that side.

In discussing the case, Dr Ober reminded his audience that spastic and flaccid paralyses occurring in the same patient are rare. Nature does not seem to strengthen the limbs of the poliomyelitis victim by superimposing a spastic paralysis. Dr William T Green stated that this boy had had his athetosis well cared for but that follow ups on this and other cases indicate that there may be a progressive muscle weakness on the affected side and possibly a recurrence of the athetosis.

The speaker of the evening was Dr Ralph K. Ghormley, of Rochester, Minnesota, whose subject was "The Life History of Bone Grafts: Experimental and clinical observations." Dr Ghormley stated that his concept that the effectiveness of the take of a graft was proportional to its permeability resulted originally from some observations on patients decalcified and subjected to straightening of their scolioses by Dr J. C. Aub.

The speed of take was determined for various bone grafts in adult dogs. Periosteal grafts showed no activity and it was concluded that this layer of bone acts merely as a limiting membrane in the adult. Cortical grafts resulted only in preosteous tissue being laid down whereas cancellous bone removed from the iliac crest showed rapid invasion by the host. It was pointed out that these transplants atrophy to some extent over a period of time and are subject to fractures during this temporary weakness. Dr Ghormley stated that the mechanism is one of metaplasia of the surrounding tissue and that chemistry and the porosity of the graft are important factors in the efficacy of the operation.

The speaker went on to describe the optimal graft for various sites. Cortical bone, especially from the tibia, was advocated for splinting of ununited long-bone fractures, scoliosis, large cystic defects, tuberculous spondylitis and spondylolisthesis. Cancellous grafts, preferably from the iliac crest, were considered suitable for lumbosacral stabilization of two vertebrae only for shelving operations in old congenital dislocation of the hip, for filling large bone cysts in combination with cortical bone and for ankylosing a hip. Osteoperiosteal grafts were held useful only in extensive scoliosis of the spinal column where the curve prevents the use of more stable transplants. The fibula due to its resistance to a shearing force, can be used to advantage for ununited fractures of the femoral neck and for replacement of the tibia in the Huntington operation. Rib grafts may be employed, suggested Dr Ghormley where scoliosis, causing severe rib deformity makes it advisable to remove ribs and replace them along the spinal column. The chip and shave grafts were called risky due to their tendency to resorb readily especially in the presence of even slight infection. Match grafts, which are merely even shaped cortical bone, were deemed satisfactory for uniting bone. "Delayed" grafts, which are left in the

donor temporarily after cutting were held to be merely another method for obtaining optimal permeability of the bone transplant.

Dr Ghormley in considering homogeneous grafts, concluded that they give less satisfactory results than autogenous ones and that the closeness of kin has no effect on the results. He was of the opinion that it is wise to match the serums preoperatively even though this has not been proved necessary. Heterogeneous grafts should be used only in those circumstances in which autogenous or homogeneous grafts are not available.

Infection was said to be the commonest complication of bone grafting. Dr Ghormley recommended waiting six months to two years after the primary infection has apparently subsided before attempting such procedures. When this complication appears after grafting, conservative treatment of the wound often leads to an ultimately good result. It was stated that the most important factor is the amount of resultant scar tissue around and between the bone fragments. Fracture may occur in the graft on malunited or ununited fractures and these should be immobilized by external fixation. Such complicating fractures may reunite in cases of scoliosis but not of tuberculosis of the spinal column.

The course of such transplants depends on the amount of invasion by the surrounding connective tissue. Usually the grafts remain in situ and are incorporated in the host bone as a result of the activity from stress and strain on the weakened part. The character of the engrafted bone remains unchanged. Grafts may occasionally be entirely absorbed for unknown reasons.

Dr Robert Osgood, during the discussion questioned whether the status of the osteoperiosteal graft had been decided in regard to its osteogenesis. He stated that it depended on one's concept of what constitutes the periosteum and consequently how much is removed. Dr Ghormley agreed and emphasized that the degree of osteogenesis is also inversely proportional to the age of the donor.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine, held at the Hotel Kenmore on February 28 was devoted to a symposium on the treatment of arthritis. The internal aspects of the subject were discussed by Dr J. Sydney Sullman. He considered the arthritides in two groups, one in which the etiology was known the other in which it was unknown. He emphasized that it was in the former group that the internist procured the best results. The striking results in the management of gonococcal arthritis with sulfanilamide and the promising results of sulfathiazol in the treatment of staphylococcal infections were mentioned. Colchicine, instead of cinchophen, was recommended for gout, since adequate relief of pain can be gained without the danger of marked toxicity.

In the treatment of arthritis of unknown cause, Dr Sullman reminded the group of the lack of a measuring stick for the evaluation of various measures. However it was believed at the Robert Breck Brigham Hospital that examination of the hemoglobin the sedimentation index, the weight of the patient and the local condition of the joints offered the best criteria for evaluation. Removal of the foci of infection was considered no more beneficial in patients with arthritis than in others and it was ad-

vocated only in cases where such a procedure would ordinarily be carried out. The anemia, which is often resistant, should be attacked by transfusions. The vitamins were found not to benefit the arthritis, even when known deficiencies were corrected. Psychotherapy was stressed as a valuable adjunct to therapy since studies have shown that in the majority of patients with rheumatoid arthritis the onset of the disease or the exacerbations are related to emotional or economic stress. Estrin may benefit a certain number of women with menopausal arthralgia if given in doses of 10,000 to 30,000 units weekly, it was stated. Bee sting, snake venom, artificial jaundice and sulfur were held to be unsatisfactory forms of treatment, while gold injections were considered too dangerous for the questionable benefit obtained.

Dr J P Bill discussed "Diet and Hygiene for the Arthritic." The speaker impressed on this audience the importance of proper clothing, heating and well-rounded diets amid cheery surroundings. Dr Bill was of the opinion that foci of infection should be diligently searched for and attacked, and that the colon was undoubtedly an underestimated source of such trouble. The manufacture of simple apparatus for applying dry heat and contrast baths in the home was described, and this type of treatment was advocated for the large group of patients who are unable to afford the orthodox methods. Dr Bill suggested a diet individualized with due regard to the idiosyncrasies of the patient and his need for added or decreased weight.

"The Use and Abuse of Physical Agents" was the title of the talk by Dr Herman A Osgood. He listed among abuses the employment of complicated methods when simpler measures are adequate, the overemphasis of one form of treatment or type of apparatus and the use of uncomfortable and even dangerous fever therapy when unnecessary. The preliminary use of heat prior to massage was advocated, with the infra red lamp being used for superficial heat and diathermy for deep heat. It was pointed out that short wave diathermy is merely a convenient form of heat and has no therapeutic specificity. Overheating may injure the cartilage if prolonged. X ray therapy may prove beneficial in rheumatoid arthritis, may relieve pain in hypertrophic arthritis and may depress the overgrowth of pannus by its action on the sensitive young cells.

The final talk of the evening, on the orthopedic aspects of the problem, was presented by Dr Loring T Swaim. The importance of proper posture as a protective measure for the proper functioning of vital organs was stressed. Recent work has shown the value of preventing rather than attempting to treat deformities of arthritis. During the acute, painful stage, plaster shells are applied to the affected part in the most comfortable approach to an overcorrection of the tendency to flexion deformities. It was found that this allows complete muscular relaxation and prevents the damaging spasm.

The striking results of these measures were demonstrated in Strumpell-Marie's disease, where jackets are applied to prevent and help correct the "poker back." Fifty per cent of an original group were found to have complicating fixation of the hips, and half of these were greatly benefited by this plaster jacket. During a five-year period, no patient treated early in the disease by this method has developed ankylosis of the hips, Dr Swaim suggested that such changes are secondary to the spine deformity. It was even claimed that some slight improvement may be brought about in already fused spines by gradual straightening of the jacket, while progression of ankylosis can certainly be retarded if not prevented.

BOOK REVIEWS

Gonorrhea in the Male and Female A book for practitioners P S Pelouze Third edition, thoroughly revised. 489 pp Philadelphia and London W B Saunders Co, 1939 \$6.00

This book has become established as the American classic on the subject, and consequently a third edition is welcomed, especially as it appears at a time when such drugs as sulfanilamide and sulfapyridine have come into widespread use in the treatment of gonorrhea. Dr Pelouze warns against too ready belief that the disease has been completely eradicated, he cites cases in which the disease recurred soon after a quick sulfanilamide "cure," and advises continuing to use the time tried proofs-of-cure before pronouncing a patient well.

In addition to urethritis and endocervicitis, Dr Pelouze goes into the various complications of gonorrhea, such as arthritis, proctitis and so forth. The section containing case histories has been omitted, but Dr Pelouze,

who is a crusader for the better control of gonorrhea and for the abolition of the taboos surrounding the whole subject, has added one on "The Medical Profession and Gonorrhea Control."

All in all this new edition, which goes thoroughly and fundamentally into all aspects both scientific and social of gonorrhea, will undoubtedly ensure the continuance of this book's pre-eminent position.

Traitement de la Blennorrhagie par le sulfamide une sulfone et leurs dérivés M. Palazzoli and F. Nitti. 195 pp. Paris Masson et Cie, 1939 35 Fr fr

Specific chemotherapy has radically changed the treatment of gonorrhea. Sulfanilamide was first used for this purpose in 1937, with results which were truly amazing. Other sulfur compounds, derivatives of sulfanilamide and developed for the most part in Europe, have been employed for this purpose. The authors of this monograph write from extensive experience in the research laboratories and clinics of the Institut Pasteur and Institut Prophylactique and Hôpital Broca of Paris. A review of former methods of treating gonorrhea admittedly ineffective, is contrasted with the brilliant results now obtained when the sulfur compounds are properly used. The action, dosage and results obtained with sulfanilamide and four of its derivatives are discussed in a convincing manner. Sulfapyridine and para-amino-benzene acetyl-sulfamide are preferred to other compounds. The small doses of all these drugs as used by the authors are of considerable interest and raise the question as to whether therapy has not been too enthusiastic in this country. This book is easily read with a minimum knowledge of French and should be studied by anybody interested in the treatment of gonorrhea.

The Employment of Fine Silk in Preference to Catgut. The advantages of transfixing tissues and vessels in controlling haemorrhage William S. Halsted. 34 pp. Boston Welch Bibliophilic Society 1939 \$3.00

Shortly before his death, Dr. William H. Welch suggested to a group of his friends that a small society be founded for the purpose of republishing medical papers and treatises of importance which were not easily available to the student or scholar. At intervals since then, the Welch Bibliophilic Society has caused to be reprinted such papers as Welch's own remarkable monograph "The Interdependence of Medicine with Other Sciences of Nature" and Holmes's "Dissertation on Acute Pericarditis."

The present publication would have delighted the society's patron. It is in many respects the most important of his great friend Halsted's publications. In it are clearly and characteristically set forth the great principles of America's greatest surgeon, namely absolute hemostasis, delicacy in the manipulation of tissues and the leaving of delicacy a minimal amount of the least irritating foreign material in the wound also included is an account of the first use of rubber gloves, gutta-percha tissue and silver foil. The exposition is based on the advantages of fine silk as a suture material for its use enforces a discipline on the surgeon which makes roughness and careless hemostasis impossible. The reappearance of this paper is timely in view of the veneration which Halsted's teachings are receiving from the clinical and laboratory researches of Reid, Whipple, Parsons, Shambaugh and Dunphy and many others.

The volume, like its predecessors, is a triumph of the bookmaker's art. The paper typography and binding are beautiful, the reproductions of Brodel's unique illustrations are excellent. It will be eagerly sought by libraries, collectors and surgeons, since the edition is limited. The

reviewer is amazed at the modest price for which the book is offered. It is to be hoped that reprintings of the first edition can be arranged so that it will become easily available to senior students and interns in surgery for whom it should be required reading.

Medical State Board Examinations Topical summaries and answers An organized review of actual questions given to medical licensing examinations throughout the United States. Harold Rypins. Fourth edition, revised. 448 pp. Philadelphia, Montreal and London J. B. Lippincott Co. 1939 \$4.50

This book was designed to assist graduates of approved medical schools to pass examinations conducted by the medical registration boards of this country.

The late author had had a long experience on these boards and also on the faculties of medical schools and was therefore qualified to approach the problems of medical education and licensure with an understanding mind. He found that some applicants for medical registration appear before examining boards handicapped by the disturbing fear of failure or in poor physical or mental condition because of faulty preparation for the ordeal.

Even though the rejection of graduates of approved medical schools does not exceed 5 per cent on the average, some worthy candidates need advice as to the best ways to prepare for the examination and the art of expression in order to satisfy the authorities of competence necessary to meet the exigencies of medical practice.

It is well explained in the text that the custom of so-called cramming and the use of stimulants immediately before an examination tend to upset the mental equilibrium of a candidate and that this may operate to his disadvantage. Another warning is expressed in the explanation that the written question and answer method does not cover the scope of the examinations as now conducted by many boards, for the candidate may be required to show familiarity with technical laboratory methods which are not susceptible of written descriptions.

Taken all together the applicant for medical licensure may study this book and profit by the advice contained therein. It is well written and informative to an unusual degree.

Treatment in General Practice The management of some major medical disorders Vol 1 and 2. 695 pp. Boston Little, Brown & Co., 1939 \$7.50.

The fact that these two volumes appeared in England over three years ago does not detract from their value, the essence of which is concise practical summaries of the treatment in most of the major medical disorders by distinguished English clinicians, many of them well known in this country. The directions for nursing care, diet, general management and convalescence, as well as the use of drugs are detailed and specific.

A satisfactory feature is to find actual prescriptions written out. It is too bad that many proprietary names are used and that references are to the British *Pharmacopoeia*. This is inconsistent with the practical and otherwise time-saving features of the edition. Though specific, some of us may question the scientific basis for certain of the prescriptions. Nevertheless, one cannot but admire the therapeutic faith of one author who suggests for hemoptysis in mitral stenosis that the coagulability of the blood may be diminished by one teaspoonful three times a day of an aqueous solution containing sodium citrate and tincture of orange peel or by applying two or three leeches over the skin of the chest and by giving a grapefruit every day.

One notices the references to treatment by manipulation, the employment of physical methods, spa treatment and climatotherapy. It seems to this reviewer that our accepted therapeutic efforts might be extended in these directions, though many of the spas and watering places mentioned in these volumes are now, unhappily, as unavailable to our English cousins as to ourselves.

One Hundred Thousand Days of Illness Dorothy Ketcham 477 pp Ann Arbor Edwards Brothers, Inc., 1939 \$2.10

Each year in the United States more than a million children are admitted to hospitals. This book traces in detail how the non-medical and social needs of these children have been met at the University Hospital, Ann Arbor, Michigan. The book is essentially an appraisal of the experience during hospitalization and subsequently of 275 patients during 100,000 days of illness over a sixteen year interval (1922-1937). It describes in great detail, often with interesting photographs, the case work, occupational therapy, special activity and library service so well organized at the hospital in question.

The book should be of especial interest to hospital social-service workers and to the librarians of hospitals. It is attractively planographed, and the design for the interesting and unusual dust jacket was made by the children themselves using finger paints.

Obstetrical Practice Alfred C. Beck Second edition. 85 pp Baltimore Williams & Wilkins Co., 1939 \$7.00

The second edition of this excellent obstetric text has brought up to date the essential advances in the subject. The results of recent research in embryology and in the physiology of menstruation and lactation have been incorporated in appropriate chapters. The reviewer was particularly impressed by the interesting arrangement of recent information regarding the physiology of the placenta, especially placental interchange. Chapter 7 on changes in the maternal organism during pregnancy is especially well done, its arrangement is excellent, and the factual material is compendiously presented.

The author presents clinical problems and their treatment in a concise, clear and authoritative manner. There are over one thousand illustrations, many diagrammatic but all of them clear and pertinent to the subject matter.

This book is a valuable source of information for the undergraduate student and for the physician in general practice. While it is too brief to be used as a reference book by the obstetrician, it contains much recent material in which he will be interested.

Nutrition and Physical Degeneration: A comparison of primitive and modern diets and their effects Weston A. Price 431 pp New York and London Paul B. Hoeber, Inc., 1939 \$5.00

'Dr. Price has written,' says Professor Earnest Hooton in his foreword, "what is often called 'a profoundly significant book.' The principal difference between Dr. Price's work and many others so labelled is that in the present instance the designation appears to be correct." With this estimate the reviewer wholeheartedly agrees. For basically simple as are Dr. Price's studies they are of fundamental importance, and his conclusions, taken at full implication, emerge as new and highly provocative of thought.

It has long been recognized that modern civilization has been attended by certain degenerative changes in man's body. Tooth decay is conspicuously rampant, together with severe malformation of the dental arches. Why should modern civilized man have such wretched teeth? Or conversely, why should his more primitive brother have such good ones? Dr. Price seems to have been the first to see that the answer to this second question might serve in great measure to answer the first. He set about to find it.

There exists a sufficiency of such primitive human material for study, scattered about the world are isolated remnants of primitive racial stocks still practically free from dental ills. Dr. Price studied groups in Switzerland, the Outer and Inner Hebrides, Alaska, parts of the United States and Canada, the islands of the south Pacific, eastern and central Africa, Australia and New Zealand, the Malay peninsula and the Amazon basin. He even investigated the ancient peoples of Peru and their descendants.

All these groups were studied in relation to their own blood relatives (when existent) who had adopted the white man's diet, as well as the Whites themselves in the same or contiguous areas. Naturally, the diets of such scattered groups appeared to vary enormously; the Eskimo must eat very differently from say, the South Sea islander, and the man of the seashore from the dweller in mountain fastnesses. Yet there must be a common dietary factor, nutritional factor, if you prefer, which ensures, apart from all climatic and geographic circumstances, an almost perfect dental status. And that factor is, says Dr. Price, an extremely liberal content in the diet of "the fat soluble activator group" of vitamins—a group, he thinks, much larger than we yet know anything about.

The most startling thing about Dr. Price's observations is that diet appears to be not merely an important but practically the sole determinant of sound teeth and regular dental arches. A mixed racial heredity—very frequently charged with a heavy responsibility—he thinks has nothing much to do with it, for the stocks which he studied, immediately on adopting the diet of modern civilized man, began to suffer from dental ills, and the very first generation born after the adoption showed invariably a high incidence not only of tooth decay but of dental malformations.

But though enough has been given here, it is hoped, to convey the importance of Dr. Price's work, no brief review can possibly do him justice. Emphatically he deserves a full reading by anybody who is concerned in any way with the scientific aspects of nutrition. Man needs to think, this book should make him.

Problems in Prison Psychiatry J. G. Wilson and M. J. Pescor 275 pp Caldwell, Idaho The Caxton Printers, Ltd., 1939 \$3.00

The application of psychiatric principles to the management of criminals has been a slow and at times discouraging task. Perhaps its greatest stimulus came when the United States Public Health Service undertook to set up psychiatric clinics in the federal prisons. This book presents briefly and clearly the story of the experiences of two of the pioneers in this undertaking. The introduction by Dr. Treadway starts us off with enthusiasm. The book is conservative and throughout constantly expresses that un-commonest of human qualities, common sense. The reader is continually conscious of the fact that the authors have been through the mill and have learned about prisoners and prisons from actual work.

AGNOGENIC MYELOID METAPLASIA OF THE SPLEEN*

A Syndrome Simulating Other More Definite Hematologic Disorders

HENRY JACKSON JR., M.D.,† FREDERIC PARKER, JR., M.D.,‡ AND HENRY M. LEMON, B.S.

BOSTON

IT IS well recognized that a varying degree of extramedullary myelopoiesis occurs in a wide variety of pathologic conditions. It has, for example, been seen in association with carcinoma metastatic to bone, it is not infrequent in certain infectious states such as scarlet fever, and it has been noted in generalized sepsis, tuberculosis of the spleen and in areas of pathologic calcification and ossification.¹ Under such circumstances, the process is of pathological interest only, for the primary underlying disease is usually patently manifest and the ectopic blood formation is minimal in amount. In myelogenous leukemia, of course, the extramedullary myelopoiesis reaches its greatest height. The liver, spleen, lymph nodes and many other organs are invaded by immature and abnormal cells of the granulocyte series. Here again, however, the process is of secondary interest to the clinician. It is true that the body as a whole is widely involved and that thereby irreparable damage is done, but the fundamental disorder is usually clearly apparent, and the diagnostic, therapeutic and prognostic implications are therefore obvious.

At this time we particularly wish to draw attention to another class of patients with myeloid metaplasia in whom this abnormal process assumes major proportions, and in whom it may therefore be responsible for serious errors in diagnosis.

In general, it may be said that these patients show a slowly progressive enlargement of the spleen, and, over a long period of time, present a blood picture which simulates that of myelogenous leukemia, or, more rarely, that of acquired hemolytic jaundice. The fact that splenectomy on

the one hand or irradiation of the spleen on the other is rarely of material benefit and is often followed by serious results indicates clearly the importance of recognizing this symptom-complex and separating it distinctly from those conditions which it may simulate. We have designated this type of myeloid metaplasia of the spleen as agnogenic.*

The literature on extramedullary myelopoiesis is large and confusing. We refer here to two papers only. Hickling² has referred to this type of myeloid metaplasia as "chronic non leukemic myelosis." He presents a review of the cases in the literature and adds 7 of his own. Hickling says, "The diagnosis of chronic non leukemic myelosis depends on the finding of immature red and white cells in the circulating blood without the great increase in the total number of leukocytes characteristic [sic] of leukemia in a patient with massive enlargement of the spleen." As will be apparent from the present study, the diagnosis is by no means so easy, indeed, without both bone marrow biopsy and splenic puncture, it is doubtful whether the diagnosis can be established during life with any degree of certainty.

Hickling's patients showed a progressive enlargement of the spleen and to a less extent of the liver, the constant presence of immature myeloid cells and nucleated red cells in the peripheral blood, basophilia, an increased indirect van den Bergh reaction in the blood serum and spontaneous hemorrhages. In 2 cases there was x-ray evidence of osteosclerosis, and Hickling lays much emphasis on this point, despite the fact that no histological evidence for such sclerosis was forthcoming in his series.

The early symptoms in his cases included abdominal pain, purpura and especially epistaxis or hematemesis. The course of the disease was slow

*From the Thorndike Memorial Laboratory the Second and Fourth (Harvard) Medical Services, the Mallory Institute of Pathology, Boston City Hospital, the Collis P. Huntington Memorial Hospital, and the Department of Medicine, Harvard University.

†Assistant professor of medicine, Harvard Medical School; associate physician, Thorndike Memorial Laboratory, Boston City Hospital, and Collis P. Huntington Memorial Hospital, Harvard University.

‡Associate professor of pathology, Harvard Medical School; pathologist-in-chief, Boston City Hospital.

This word, derived from the Greek, was suggested by Dr. Robert M. G. Coe, and means of unknown or uncertain etiology.

Of his 7 patients, 5 were alive and in reasonably good health from two to seventeen years from the date of the first symptom. Two patients died, one following a short febrile illness thirteen years after onset, and the other following ligation of the splenic pedicle nineteen years after the first symptoms. Hickling very properly warns against splenectomy, and points out that of the 27 patients reported in the literature who were subjected to this procedure, 15 died within a few days of operation.

Histological examinations were made in only 3 of Hickling's cases. In his second case, a spleneculus removed at operation showed myeloid metaplasia of the pulp without involvement of the Malpighian bodies. In his third case, there was myeloid metaplasia of the spleen and liver and an "intensely active" marrow was found in the lower end of the femur. In his fourth case, he found myeloid metaplasia of the spleen, liver, kidneys, lymph nodes and skin. The bone marrow appeared normal.

Vaughan and Harrison³ have described 2 somewhat similar cases in which there was splenomegaly, increased red-cell fragility, a leukemoid blood picture and eventually a profound anemia. In both cases there was an initial polycythemia. In both there were osteoporosis and extensive fibrosis of the bone marrow. They suggest that "polycythemia vera, megakaryocytic leukemia and myelosclerosis with leukoerythroblastic anemia form a group of closely related conditions." Vaughan, too, warns that "if sclerosis of the marrow is present, x-ray or radium treatment would appear to be contraindicated."

We here report 10 cases proved by histological examinations to have had extensive myeloid metaplasia, especially of the spleen. In all, the onset was insidious and the course slow. In 9, the clinical and hematologic picture simulated that of myelogenous leukemia. One case was erroneously diagnosed as hemolytic jaundice. In all cases, foci of young myeloid cells and megakaryocytes were present in the enlarged and fibrosed spleen and this organ was the chief, though not the only, site of the ectopic blood formation. In the majority of these spleens were found, in addition, isolated clusters of immature red blood cells.

In 3 cases irradiation was applied to the spleen, two of these patients died within a few weeks, the third was not materially helped and died two years later. Three splenectomies were performed. Two of the patients died within six weeks, the third was not improved and died a year later of generalized sepsis.

Autopsies were performed on 6 of the 10 pa-

tients. Splenic punctures and bone-marrow biopsies were carried out on 3 of the remaining cases, and splenectomy on 1.

It is obvious that from a pathological as well as a clinical standpoint the disease from which this symptom complex must most often be differentiated is chronic myelogenous leukemia.

The spleen in agnogenic myeloid metaplasia shows fibrosis varying in degree from slight to marked. Occurring in isolated foci are found hematopoietic cells of various types. Myelocytes and other early forms of the granulocytic series are constantly found. Collections of nucleated red cells or earlier forms of the same series may be present. As a rule megakaryocytes are found, and they are often present in large numbers. The Malpighian corpuscles are preserved, although they may contain an occasional myelocyte or megakaryocyte. Hemosiderin in macrophages may be present, often in considerable amount.

In contrast, a spleen from a case of leukemia that has received no irradiation therapy is characterized by a marked diffuse infiltration by immature cells of the granulocytic series. Young red cells may or may not be present and are seldom a prominent feature. Megakaryocytes are usually seen. The Malpighian corpuscles are as a rule completely obliterated. Infarcts are extremely common. If a case has been irradiated, the histologic picture in the spleen is complicated by the appearance of fibrosis, which may be considerable in amount. In making a differential diagnosis between myeloid metaplasia and myelogenous leukemia on such a spleen, one must depend mainly on the persistence or loss of the Malpighian corpuscles and the absence or presence of infarcts. Thus it is evident that a positive differential diagnosis can usually be made on a section of spleen, but not on a specimen obtained by splenic puncture alone, for in the latter only the separate cytological elements can be studied and not the general architecture of the organ. The evidence obtained from a splenic puncture may, however, be combined with that obtained from bone-marrow and hematological studies to make a definite diagnosis.

The bone marrow from patients with leukemia shows a diffuse infiltration of immature cells of the granulocytic series and a marked decrease in the red-cell series. Fat tissue is usually absent. In myeloid metaplasia, on the other hand, the picture varies greatly. The marrow may appear normal, aplastic, hyperplastic or fibrotic, but in no instance have we seen a change which could be confused with that of leukemia.

The liver in leukemia is characterized by extensive infiltration of the portal areas by young gran-

ulocytes with, in addition, numerous similar cells in the sinusoids. In myeloid metaplasia the picture varies considerably, but usually consists of focal collections in the sinusoids of cells of the granulocytic or red-cell series. Megakaryocytes are commonly present.

The lymph nodes in leukemia usually show a diffuse infiltration of the sinuses and cords with immature granulocytes. Foci of red-cell formation and megakaryocytes may or may not be present. In myeloid metaplasia, isolated collections of young granulocytes, immature red cells and megakaryocytes may occur. The process, however, is not diffuse as it is in leukemia.

In leukemia, there is frequently an infiltration of many other organs, such as the kidney and heart. In myeloid metaplasia on the other hand, the occurrence in these organs of hematopoietic cells is very rare and they are never present in a significant number.

In brief, then, the main difference between the histological picture of leukemia and that of myeloid metaplasia is the diffuse, neoplastic like infiltration in the former, as contrasted with the localized and focal aggregations of hematopoietic cells in the latter. It should be emphasized once more that the bone marrow in myeloid metaplasia never shows the histologic features usually considered diagnostic of leukemia.

Thus it is clear that the pathological differential diagnosis between leukemia and myeloid metaplasia can be made without difficulty on autopsy material or on a spleen that can be examined histologically. It is equally clear that a specimen removed by splenic puncture can merely furnish information as to the presence or absence of hematopoietic cells, and that a differential diagnosis from leukemia cannot be made by this procedure alone. The findings of such myeloid cells in a splenic puncture together with histologic evidence that the bone marrow is not leukemic is, however, sufficient for a diagnosis of myeloid metaplasia.

The following cases illustrate the clinical and pathologic characteristics of the condition.

CASE 1 (No. 745,095). A. M., a 63-year-old woman, was admitted to the hospital on April 18 1934. For 8 weeks she had grown progressively weaker and had suffered from increasing dyspnea, palpitation and nausea. Six weeks before entry she had noticed that her scleras and skin were markedly yellow. One week before admission she had fainted.

Her past history was essentially negative, except that she had been "pale" all her life, and for 6 years prior to entry had noticed a slight though definite yellowish tinge to her skin. The family history was irrelevant. In particular none of the siblings had had jaundice.

Physical examination disclosed a pale, obese and jaun-

diced woman. Both the scleras and skin were definitely icteric. The mucous membranes were pale; the tongue appeared normal. The heart was enlarged 1 cm. to the left of the midclavicular line, and there was a harsh blowing systolic murmur over the entire precordium. The liver was just palpable on inspiration; the spleen was felt 6 cm. below the costal margin.

Both urobilin and urobilinogen tests on the urine were strongly positive. The stools showed the presence of bile and occult blood. The red-cell count was 820,000, the hemoglobin 20 per cent (Sahl) or 3.12 gm. per 100 cc., and the white-cell count 27,000 with 80 per cent polymorphonuclears, 10 per cent myelocytes, 2 per cent stem cells, 6 per cent lymphocytes and 2 per cent monocytes. There were marked poikilocytosis and anisocytosis, and many nucleated red blood cells were seen in the smear. There were 38 per cent reticulocytes. The hematocrit reading was 11.4 per cent. The mean corpuscular volume was 138.8 cu. microns, the mean corpuscular hemoglobin concentration 27.4 per cent and the mean corpuscular hemoglobin 38 micro-microns. Blood platelets were normal in number and appearance. The icteric index was 50. The indirect van den Bergh reaction was positive. Gastric analysis showed no free hydrochloric acid even after the administration of histamine. Fragility tests showed a moderate increase in the susceptibility of the red cells to hemolysis by hypotonic solutions of sodium chloride. Hemolysis began at 0.54 and was complete at 0.30.

A tentative diagnosis of acquired hemolytic jaundice was made.

On May 10 a sternal bone marrow biopsy (JP 108) showed numerous stem cells, erythroblasts, normoblasts and nucleated red cells. A moderate number of granulocytes and megakaryocytes were also present. These findings while not diagnostic, were considered consistent with hemolytic jaundice. Following a blood transfusion the red-cell count rose to 2,100,000, the hemoglobin to 50 per cent (Sahl) or 7.8 gm. per 100 cc. and the reticulocytes to 45 per cent.

On June 12 2 months after admission the fragility of the red cells had further increased hemolysis beginning at 0.66 and being complete at 0.28. The icteric index coincidentally fell to 17. Two further transfusions of blood were given. The patient's strength and general condition improved and on August 30 a splenectomy was performed. The spleen (S-34-3007) weighed 1240 gm. The capsule was smooth and the consistency firm. On section the cut surface was uniformly dark red and neither the Malpighian corpuscles nor trabeculae were prominent. Microscopically there was diffuse fibrosis. Focal areas of myelocytes with rare adult granulocytes were prominent. Numerous foci of red-cell formation were present. In addition, scattered throughout the organ were a large number of megakaryocytes. The Malpighian corpuscles were for the most part well preserved. The histologic picture in no way suggested that usually seen in hemolytic jaundice and often considered diagnostic of that disease.¹ The patient died 3 days after operation.

Autopsy (A 34-494) showed generalized peritonitis, chronic cholecystitis with cholelithiasis, nephrolithiasis, and hepatomegaly. The liver weighed 2050 gm. and microscopically showed hemosiderosis of a moderate degree and some fat in the liver cells. The vertebral sternal and mid femoral marrows were all hyperplastic, and all series of blood cells were well represented with normal maturation. No lymph nodes were examined.

Comment. Here, then, was a patient who, over a period of at least 6 years, had had slight jaundice and weakness and who entered the hospital with the clinical and labora-

tory findings usually considered diagnostic of hemolytic jaundice. Yet the seemingly justifiable splenectomy was followed shortly by death, and the spleen failed to show the lesions of this disease, but revealed instead only marked myeloid metaplasia

CASE 2 (No 566,172) E H, a 52-year-old man, entered the hospital on July 2, 1928. Twelve years prior to entry he began to feel generally weak and "sick." At the same time there developed on the right great toe and on the dorsum of the left foot small areas of gangrene, which cleared gradually when treated with "dilute carbolic acid," in spite of the fact that amputation had been deemed necessary by an eminent specialist in vascular diseases. At the same time, the patient was told that his blood was "too thick," and he was advised to follow a special diet to remedy this defect. Shortly thereafter he noticed that his hands and feet constantly felt cold. The general weakness gradually increased, and in 1925 he was sufficiently ill to be confined to bed for a period of 2 months. His weakness had become extreme and he was slightly dyspneic, even at rest. It was at this time that the enlarged spleen was first noted.

The past history was uneventful, except that he had had malaria at the age of 18.

On entry to the hospital in 1928, physical examination showed a moderate degree of pallor of the mucous membranes. There was no lymphadenopathy. The lungs were clear. The heart was normal in size, but the sounds were of poor quality and there were many ventricular extrasystoles. The blood pressure was 120/70, the peripheral vessels were thickened and sclerotic. The abdomen was markedly distended and was almost filled by the enormously enlarged liver and spleen, the former reaching to the level of the umbilicus, the latter descending into the pelvis. Both organs were extremely hard.

The red-cell count was 3,400,000, the hemoglobin 83 per cent (Sahl) or 12.95 gm per 100 cc., and the white-cell count 23,700, with 79 per cent polymorphonuclears, 6 per cent metamyelocytes, 7 per cent myelocytes, 5 per cent lymphocytes and 3 per cent monocytes. The platelets were normal. X-ray films of the long bones showed no abnormalities. The basal metabolic rate was +47 per cent, and a blood Hinton test was positive. Careful questioning revealed no history of luetic infection.

A diagnosis of myelogenous leukemia was made, and 200 r was given over the spleen. As a result of this small dose of x-ray, the white-cell count dropped to 8200, the differential count remaining essentially the same, and the basal metabolic rate fell to +19 per cent. Neither the liver nor the spleen decreased in size. Further x-ray treatment was withheld, and the patient left the hospital somewhat disgruntled because he had not had his "full share" of irradiation.

He returned, however, 4 years later and was readmitted on May 12, 1932, again complaining of weakness, which had become so marked that he was unable to work. In the 4 years since his discharge he had had a number of brisk nosebleeds, and latterly had noted edema of the ankles toward the end of the day. He had received no specific therapy.

At the time of the second admission the patient was found to be dyspneic, even at rest. There had been considerable weight loss. The liver and spleen were still grossly enlarged and very hard. The red-cell count was 1,900,000, the hemoglobin 44 per cent (Sahl) or 6.86 gm per 100 cc., and the white-cell count 6300, with 50 per cent polymorphonuclears, 19 per cent myelocytes, 8 per cent promyelocytes, 2 per cent stem cells, 6 per cent monocytes and 15 per cent lymphocytes. The platelets were

definitely diminished in number and 5 nucleated red cells were seen on counting 100 white cells.

On May 16 200 r was given to the spleen, followed by a severe reaction with dizziness, vomiting, great weakness and a severe nosebleed. On May 23 another dose of 200 r was given over the spleen, with marked diminution in its size but very little amelioration of symptoms. Physical examination revealed the presence of ascites, and 800 cc. of thin, blood tinged fluid was withdrawn from the peritoneal cavity. The patient failed rapidly. The red-cell count fell to 1,070,000, the hemoglobin to 25 per cent (Sahl) or 3.9 gm per 100 cc., and the white-cell count to 3050, with the differential count essentially as before. The patient died June 27, 1932, 16 years after the first symptom of his disease and 5 weeks after his final x-ray therapy.

Autopsy (PA-32 65) showed a small amount of clear fluid in both pleural cavities and fibrous adhesions at both lung bases. The heart was normal. In the peritoneal cavity was 900 cc. of bloody fluid. The spleen weighed 4600 gm and cut with greatly increased resistance. The liver weighed 4400 gm, and similarly was very firm. There was definite enlargement of the mediastinal, para-aortic and mesenteric nodes. Grossly the bone marrow appeared normal.

Microscopically the spleen showed marked fibrous thickening of the capsule and pulp. There were many isolated foci of myelocytes. Nucleated red cells were numerous, but less mature forms were few. Megakaryocytes were rare. Phagocytosis of red cells by macrophages was a prominent feature. The Malpighian corpuscles were intact. In the liver, there were scattered immature cells of the granulocytic series in the sinusoids. Neither nucleated red cells nor megakaryocytes were present. The mediastinal and abdominal lymph nodes contained isolated foci of stem cells and myelocytes. Numerous nucleated red cells were present, and a few clumps of erythroblasts. There were many megakaryocytes. The lymph sinuses contained a few macrophages filled with red cells. The vertebral bone marrow showed a considerable degree of fibrosis. A few stem cells and myelocytes were present. There were large numbers of nucleated red cells and rare less adult forms. Megakaryocytes were few. A moderate number of macrophages containing numerous red cells were noted. The histological picture was, therefore, in no way suggestive of leukemia, and what little activity remained appeared to be confined mainly to the red-cell series.

Comment This patient for many years had a greatly enlarged liver and spleen and was found to have a peripheral blood picture very suggestive of myelogenous leukemia. Apparent confirmation of this diagnosis was found in the elevated basal metabolism. Yet a very small amount of radiation produced a rather marked fall in the white-cell count, and subsequent moderate irradiation to the spleen was followed by rapidly developing anemia and death. Autopsy showed extramedullary myeloid metaplasia of the spleen and a fibrotic bone marrow. There was no evidence of leukemia.

CASE 3 (No H 17 199.93) W R., a 60-year-old man, was first seen on May 2, 1917. For 20 years he had complained of postprandial distress in the left upper quadrant, for "many years" he had noticed a mass in the same region. For 12 months prior to entry he had felt tired and worn out. Six months later his own doctor had substantiated the fact that his spleen was enlarged.

The past and family histories were irrelevant. On entry to the hospital, physical examination was es-

essentially normal, except that the liver was just palpable on inspiration and the spleen extended 7 cm. below the umbilical line on quiet respiration.

The red-cell count was 4,830,000 the hemoglobin 90 per cent (Sahli) or 13.9 gm. per 100 cc., and the white cell count 13,100 with 70 per cent polymorphonuclears 10 per cent myelocytes, 2 per cent stem cells, 4 per cent monocytes and 14 per cent lymphocytes. Five nucleated red cells were seen while counting 100 white cells, and there was marked anisocytosis, poikilocytosis and polychromatophilia. The platelets were greatly decreased in number. A diagnosis of myelogenous leukemia was made, and 6120 mc. hr. of radium was applied over the spleen at a distance of 5 cm. with 5 mm. of lead screening. Five days later the hemoglobin had fallen to 78 per cent, and the white-cell count to 6000. The differential count was essentially as before. The spleen was slightly but definitely smaller than on admission.

No further therapy was undertaken but on June 7 1 month after the initial radium treatment, the red-cell count had fallen to 1,700,000 the hemoglobin to 35 per cent and the white-cell count to 4000. A differential count revealed 54 per cent polymorphonuclears 14 per cent myelocytes, 14 per cent stem cells and 18 per cent lymphocytes. The reticulocytes were but 0.1 per cent. The platelets had become still further reduced in number. Definite jaundice was noted for the first time. The spleen continued to recede, but the patient, after a short interval of slightly improved health failed rapidly and died on July 19 1917 6 weeks after radium treatment.

Autopsy (HA 17-85) showed the spleen extending to the umbilicus and weighing 2200 gm. and the liver reaching 6 cm. below the costal margin and weighing 2700 gm. There was an enlargement of the lymph nodes in any region. Microscopically the spleen showed a marked diffuse fibrosis. Fairly numerous foci of stem cells, myelocytes and more adult granulocytes were present. There was no red-cell formation and there were no nucleated red cells. A considerable number of megakaryocytes were noted. The Malpighian corpuscles were preserved, but were diminished in size and often contained an occasional myelocyte. There were a moderate number of lymphocytes and plasma cells in the pulp and in addition a considerable number of hemosiderin-laden macrophages. The sinusoids of the liver contained a moderate number of myelocytes and megakaryocytes, but no nucleated red cells. The bone marrow from the vertebrae, sternum femur and tibia was almost completely aplastic, with but a few isolated cells of the granulocytic series present.

Comment. This case also presented, when first seen the clinical and hematologic features not inconsistent with a diagnosis of myelogenous leukemia. Irradiation to the spleen however was followed, as in Case 2, by rapid decline and early death. Autopsy showed an aplastic fatty marrow and marked myeloid metaplasia of the spleen. It seems not improbable that in this case and in the preceding one the greatest part of the blood formation was taking place in the spleen and that irradiation of this organ with consequent destruction of immature cells led to a rapidly developing anemia leukopenia and death.

CASE 4 (No. T 959) L. J., a 51 year-old white woman was admitted to the hospital on September 22 1931. In 1901 she had had tertian malaria. In 1906 she had had a severe attack of jaundice associated with anorexia vertigo headache and vomiting. This illness lasted for 2 months, and in the next 17 years she had three other similar episodes. In 1915 she was operated on for acute appendicitis. No mention of the spleen was made in the operative

notes, but it was stated that the ovaries were under developed and subsequently she ceased to menstruate. In 1928 eight years prior to admission the patient suffered from a profuse hemorrhage following the extraction of an abscessed tooth. In 1936 she vomited a large amount of blood on two occasions. An abdominal exploration was done. A gastric ulcer was said to have been found and a posterior gastroenterostomy was performed. In 1929 the patient complained of soreness of the tongue and loss of sensation of taste. From that time on she did not feel well and complained of attacks of dizziness and vomiting.

The family history was irrelevant.

Physical examination on entry to the hospital in 1931 showed a middle-aged, pale woman in no apparent distress. There was no jaundice. The tongue was markedly atrophic and somewhat redder than normal. The spleen was found 4 cm. below the costal margin. The liver could not be felt. The red-cell count was 5,300,000 the hemoglobin 57 per cent (Sahli) or 8.89 gm. per 100 cc. and the white-cell count 28,500 with 70 per cent polymorphonuclears, 1 per cent metamyelocytes 10 per cent myelocytes, 2 per cent stem cells, 11 per cent lymphocytes, 3.5 per cent monocytes and 2.5 per cent basophils. Five nucleated red blood cells were seen while counting 100 white cells. The reticulocytes were 5 per cent. The platelets were greatly increased, and many nucleated reds were seen in the smear. Gastric analysis showed no free hydrochloric acid even after the administration of histamine, and the gastric index was 9. The red-cell fragility began at 0.52 and was complete at 0.24.

A diagnosis of early myelogenous leukemia or atypical hemolytic jaundice was made, and the patient was put on massive doses of iron and ammonium citrate. Possibly as a result of this therapy the red-cell count rose to 7,600,000 and the hemoglobin to 110 per cent (Sahli) or 17.16 gm. per 100 cc. The white-cell count remained elevated, and the smear continued to show a definite though varying per cent of myelocytes, myeloblasts and nucleated red cells.

On December 9 the red-cell count was 7,680,000 the hemoglobin 104 per cent (Sahli) or 16.22 gm. per 100 cc. and the white-cell count 28,000 with 80 per cent polymorphonuclears, 3 per cent myelocytes, 1 per cent stem cells 3 per cent basophils, 1 per cent monocytes, and 12 per cent lymphocytes. The platelets were markedly increased in number.

A biopsy (S-33-407) of the sternal marrow in February 1933 showed patchy fibrosis. In the fibrotic areas, hematopoietic cells were few. Elsewhere the hematopoietic tissue was cellular and was composed of the granulocytic series and numerous megakaryocytes. Red-cell formation was comparatively slight. The patient continued to complain of vague paresthesias of the hands and feet, sore tongue and malaise, but her general condition remained fairly good.

In the latter part of 1932, the immature white cells in the peripheral blood became more numerous. On October 17 1932 the red-cell count was 5,320,000, the hemoglobin 91 per cent (Sahli) or 14.20 gm. per 100 cc., and the white-cell count 9700 with 81 per cent polymorphonuclears, 3 per cent eosinophils 1 per cent basophils, 14 per cent myelocytes and 1 per cent stem cells. Five nucleated red cells and 1 normoblast were seen in counting 100 white blood cells. The mean corpuscular volume was 86.2 cu. microns, the mean corpuscular hemoglobin concentration 32.3 per cent, the mean corpuscular hemoglobin 26.7 micro-microgm. and the hematocrit reading 45.9 per cent.

In November 1935 the patient developed generalized joint pains, and x-ray films showed some hyperostotic arthritis about the right knee joint. She had failed con-

siderably in strength. The peripheral blood picture remained essentially as before, and the spleen was now palpable nearly to the umbilicus and was very hard in consistency.

The course of the disease slowly continued to advance and early in April, 1937, the patient had an attack of very severe pain in the right great toe, associated with marked redness and tenderness. The blood uric acid was 4.2 mg per 100 cc. The pain subsided without specific therapy in the course of a week.

In June, 1938, a second sternal bone marrow biopsy (S-38-1753) was performed. The bone marrow showed a greater degree of fibrosis than that seen in the first biopsy specimen. Scattered myelocytes, polymorphonuclear leukocytes and megakaryocytes were present, but were few in number. No red-cell formation was evident.

From this time on the patient's condition became progressively worse. There were no further hemorrhages, yet by January, 1939, the red-cell count had fallen to 3,700,000 and the hemoglobin to 50 per cent (Sahli) or 7.80 gm per 100 cc. The white-cell count was 16,500, with 51 per cent polymorphonuclears, 2 per cent basophils, 3 per cent metamyelocytes, 13 per cent myelocytes, 4 per cent stem cells, 8 per cent monocytes and 19 per cent lymphocytes. The red-cell diameter was 6.84 microns. Forty-six nucleated red cells and 3 normoblasts were seen in counting 100 white cells. The platelets were markedly decreased in number. At this time, a splenic puncture was done and large numbers of myelocytes, promyelocytes, stem cells, nucleated red cells, normoblasts, erythroblasts and megakaryocytes were found.

Comment. This patient has shown for a period of at least 8 years features suggestive of myelogenous leukemia, namely an enlarged spleen, an elevated white-cell count and the presence in the peripheral blood of notable numbers of myelocytes, nucleated red cells and occasional stem cells. Certain findings such as the slightly increased red-cell fragility and the subclinical icterus were reminiscent of hemolytic jaundice. At one period when the red-cell count was over 7,000,000 polycythemia vera was considered as a distinct diagnostic possibility. Yet on two occasions bone marrow biopsy failed to substantiate any of these diagnoses and splenic puncture revealed the presence of myeloid metaplasia. The onset of the disease was insidious; indeed, it is difficult to state with any degree of assurance when the condition started, though it is probable that the profuse hemorrhage following a tooth extraction 16 years previously should be taken as the first evidence of its existence.

In view of the disastrous results of splenectomy in Case 1, which had been diagnosed as hemolytic jaundice, and the apparently unfortunate effects of irradiation in Cases 2 and 3, which had erroneously been diagnosed as myelogenous leukemia, it is perhaps fortunate that this patient was treated symptomatically only.

DISCUSSION

From a clinical and hematological point of view, these cases of agnogenic myeloid metaplasia of the spleen are most frequently confused with myelogenous leukemia in the subleukemic phase. More rarely they simulate classical myelogenous leukemia with comparatively high total white-cell counts. Still more rarely acquired hemolytic jaundice is imitated. In view of the apparent wisdom of treating these cases symptomatically only, the question naturally arises as to how they

may be distinguished during life from these other more definite clinical entities. It is already apparent that such differentiation can, with assurance, be made only by combined hematological, clinical and pathological studies.

The total number of white cells in the peripheral blood varies, though it is usually moderately increased. Varying numbers of myelocytes and stem cells constantly occur in the peripheral blood, but the hematologic hiatus so suggestive of acute leukemia is not seen. The peripheral blood picture by itself is not distinctive.

The anemia, which may be normocytic, microcytic or macrocytic, varies in degree. It is usually moderate, rarely extreme. Except in those cases simulating hemolytic jaundice, the reticulocytes are not greatly increased. Nucleated red cells and more rarely normoblasts are found almost constantly in the peripheral blood stream. In certain cases some degree of polycythemia may exist in the early stages of the disease. It is possible that some cases of so-called polycythemia may actually belong in this class. The platelets may be increased, normal or decreased. The onset is insidious, the course slowly progressive.

The commonest symptoms are weakness, joint pains, anorexia, abdominal pain, epistaxis and loss of weight. The spleen is enlarged, often greatly so, and the liver is frequently increased in size. Both organs are of very firm consistence. Generalized lymphadenopathy does not occur. Slight jaundice is common.

During life, the condition may be suspected when a patient with a large spleen has had, over a considerable period of time, a subleukemic peripheral blood picture, together with occasional nucleated red cells in the smear. This suspicion becomes a probability if the spleen is very large and hard, slight jaundice is present, the course of the disease is slow and the total white-cell count is comparatively low. The disease may be properly diagnosed when, under these conditions, bone-marrow biopsy fails to reveal the pathologic changes characteristic of leukemia and splenic puncture shows the presence of megakaryocytes and immature cells of both the red-cell and white-cell series. Should the peripheral blood be suggestive and the bone marrow prove to be non-leukemic, splenic puncture is necessary in order to rule out those conditions in which splenectomy might be indicated, if only as a last resort.

The nature of the condition appears at present entirely obscure. For one reason or another, the bone marrow seems unable to form and deliver the requisite number of blood cells, but in view of the fact that at the height of the disease or

at death the bone marrow may be on histological examination normal, fibrotic, fatty or hyperplastic, it is by no means certain that bone marrow failure is the primary lesion. Vaughan⁴ has suggested that the "leukoerythroblastic hyperplasia" and the marrow sclerosis are processes which occur simultaneously in response to a single stimulus. It is difficult to reconcile this hypothesis with the extremely varied marrow pictures, which do not always include sclerosis, and for

neither case was there any improvement in the peripheral blood picture, and both patients died within a year.

In 4 cases a definite diagnosis of myelogenous leukemia was made. One patient was treated symptomatically and died three years from onset. The three others were given x-ray treatment. Two died within six weeks, in the third case no real benefit occurred and the patient succumbed to bronchopneumonia two years later.

TABLE I

| CASE NO. | AGE | SEX | DURATION | | | RED- BLOOD-CELL COUNT $\times 10^6$ | WHITE BLOOD-CELL COUNT $\times 10^6$ | TREATMENT | CONDITION OF BONE MARROW | ICTERIC INDEX | RETICULO- CYTES % |
|----------|-----|-----|------------|-------------|-------------------------|--|---|-------------|-----------------------------|------------------|-------------------------|
| | | | TO DATE | TO DEATH | AFTER TREAT- MENT | | | | | | |

| 8 | 2 | M | — | 7 | mo. | 3.9-3.0 | 12.0-70.0 | Splenectomy | — | 9 | 1-2 |
| 9 | 64 | F | — | 5 | 3 y. | 3.9-2.5 | 11.0-36.0 | X-ray | Osteoclastic | — | 1-7 |
| 10 | 52 | M | 22 mo. | — | — | 7.5-4.5 | 14.0 | Symptomatic | Fibrotic | 3 | 3.1 |

This patient had had small amount of irradiation 4 years previously

the present we must rest content with the knowledge that massive extramedullary myelopoiesis may occur, and that more definite hematologic disorders may thereby be simulated.

CONCLUSIONS

A total of 10 cases of agnogenic myeloid metaplasia are presented (Table I).

In all instances, the spleen showed marked myeloid metaplasia, namely scattered foci of immature red and white blood cells and megakaryocytes throughout a slightly or markedly fibrosed organ. In the cases that came to autopsy there were occasionally found similar foci of ectopic blood formation in the liver and lymph nodes. There was not the uniform distribution of immature cells seen in the organs of leukemic patients, and immature cells of the red-cell series were present in greater numbers than in that disease. The Malpighian corpuscles were for the most part uninvolved. The bone marrow was variously fibrotic, hyperplastic, aplastic or normal. In no instance was it even suggestive of leukemia.

In 3 cases the diagnosis of myeloid metaplasia seemed clearly established and treatment was symptomatic only. All three patients are alive. In 1, a diagnosis of hemolytic jaundice was made and splenectomy was performed. The patient died three days postoperatively.

In 2 cases no definite diagnosis was made, but splenectomy was advised and carried out. In

The average duration from onset to date of death was 10.8 years. In 4 cases the symptoms dated back over fifteen years.

The chief symptoms were weakness, abdominal distress and a hemorrhagic tendency.

The principal findings were a progressive enlargement of the spleen, a moderately elevated or slightly depressed white-cell count and the constant presence of immature red and white cells in the peripheral blood.

In view of the apparent uselessness and possible harm arising from irradiation or splenectomy, it is of the greatest importance to recognize this condition and to undertake only symptomatic and supportive treatment when it has been proved to be present.

ABSTRACTS OF THE REMAINING FIVE CASES

CASE 5 (No. 914,393). M. G., a 49-year-old man, was admitted on October 11, 1937 with the complaint that for 4 months he had noticed a painless lump in the left upper quadrant of the abdomen. There were no other symptoms.

On physical examination, the spleen was 14 cm. and the liver 8 cm. below the costal margin. The red-cell count was 3,980,000, the hemoglobin 70 per cent (Sahli) or 10.92 gm. per 100 cc., and the white-cell count 8600 with 18 per

cent polymorphonuclears, 22 per cent young polymorphonuclears, 5 per cent metamyelocytes, 21 per cent myelocytes, 3 per cent stem cells, 25 per cent lymphocytes and 6 per cent monocytes. The platelets were decreased in number, and in counting 100 white blood cells 8 nucleated red cells and 1 normoblast were seen. Both anisocytosis and poikilocytosis were marked. The hematocrit reading was 33.3 per cent, the mean corpuscular volume 83.6 cu microns, the mean corpuscular hemoglobin concentration 33.8 per cent and the mean corpuscular hemoglobin 27.4 micro-microgm. The icteric index was 10. On two occasions the basal metabolic rate was +50 per cent.

A sternal bone marrow biopsy (S-37-3415) showed extensive fibrosis. Very rare scattered myelocytes and megakaryocytes were found in the dense connective tissue. There was no evidence of red-cell formation. No specific therapy was given. A splenic puncture performed on November 10, 1938, showed a marked degree of myeloid metaplasia. To date the patient's condition has remained essentially the same.

CASE 6* G. C., a 30-year-old woman, was first seen on March 21, 1934. Seventeen years previously a physician had found her spleen enlarged. She had remained in fairly good health until 1930, when she began to complain of increasing weakness and some bleeding from the gums. Physical examination in March, 1930, revealed a spleen which descended to the level of the umbilicus. The red-cell count was 3,190,000, the hemoglobin 60 per cent (Sahl) or 9.3 gm. per 100 cc., and the white-cell count 7000, with 65 per cent polymorphonuclears, 10 per cent young polymorphonuclears, 3 per cent myelocytes, 17 per cent lymphocytes, 2 per cent basophils and 3 per cent eosinophils.

Early in 1935 the patient began to suffer from attacks of right lower quadrant pain, and in June, 1936, the white-cell count had risen to 53,000, with 53 per cent polymorphonuclears, 17 per cent metamyelocytes, 3 per cent myelocytes, 6 per cent eosinophils, 1 per cent basophils and 20 per cent lymphocytes. The red cell count was 4,100,000. The reticulocyte count was 5 per cent, and 6 nucleated red cells were seen in counting 100 white blood cells.

Early in 1937 a splenectomy was performed. The spleen (S-36-3890) weighed 1100 gm. and showed marked fibrosis and myeloid metaplasia. Following operation, there was no essential change in the patient's condition. She eventually developed a bacteremia and septicemia from which she died in the middle of 1938.

Autopsy (S-38-2553) revealed the usual picture of staphylococcal septicemia with multiple abscesses of the lungs. Microscopically the liver showed a slight increase in the periportal connective tissue. There were a moderate number of myelocytes in the portal areas and in the sinusoids. No nucleated red cells or evidence of red-cell formation was seen. Megakaryocytes were present in large numbers in the sinusoids. The bone marrow showed no fat tissue, but was filled with hematopoietic tissue. Although the marrow was highly cellular, it in no way suggested leukemia.

CASE 7 (No. 692,414) A. B., a 70-year-old woman, was admitted on December 7, 1932. In 1930 she had noticed increasing fatigability and anorexia. In 1931, the weakness increased and she became increasingly dyspneic on exertion. On physical examination in 1931 the mucous membranes were pale. The spleen was palpable 2 cm. below the costal margin. The red-cell count was 2,000,000, the hemoglobin 28 per cent (Sahl) or 4.37 gm. per 100 cc., and the white-cell count 18,900, with 46 per cent poly-

morphonuclears, 7 per cent myelocytes, 35 per cent lymphocytes, 8 per cent monocytes, 3 per cent basophils and 1 per cent eosinophils. The reticulocyte count was 10 per cent, and 10 nucleated red cells were seen on counting 100 white blood cells. A fragility test showed a trace of hemolysis at 0.56 and complete hemolysis at 0.30. The hematocrit reading was 15.6 per cent, the mean corpuscular volume 78 cu microns, the mean corpuscular hemoglobin concentration 28 per cent, and the mean corpuscular hemoglobin 21.9 micro-microgm.

Throughout her short stay in the hospital, the patient ran an irregular temperature from 99 to 101°F. She failed rapidly, and on January 30, 1933, the red-cell count had fallen to 925,000, the hemoglobin to 13 per cent (Sahl) or 2.03 gm. per 100 cc., and the white-cell count to 1300. The differential count remained essentially the same. The patient died February 3, 1933.

Autopsy (A 33-109) revealed nothing of note grossly, with the exception of chronic cholecystitis with cholelithiasis. The spleen weighed 410 gm. Microscopically it showed a slight degree of diffuse fibrosis and marked myeloid metaplasia. The liver weighed 1340 gm. and grossly was not remarkable. A moderate number of stem cells occurred scattered and in clumps in the sinusoids. Several foci of immature red cells and fairly numerous megakaryocytes could be recognized also in the sinusoids. The vertebral bone marrow had patchy areas of fibrosis. Where the fibrosis was marked, only a few hematopoietic cells were present, elsewhere they were numerous. Of the granulocytic series, stem cells, myelocytes and adult granulocytes were numerous. The red-cell series was represented by clumps of stem cells and erythroblasts, occasional normoblasts and rare nucleated red cells. Megakaryocytes were numerous, many of them young. A considerable amount of hemosiderin was present, especially in the fibrotic areas. The sternal bone marrow showed a moderate amount of fibrosis.

CASE 8 (No. T-988) S. S., a 22-year-old medical student, noted during routine classwork in June, 1926, that his own blood smear was abnormal, in that the red cells showed considerable variation in size and shape and that myelocytes were present. In 1925, on routine physical examination, it had been noted that his spleen was easily palpable.

Physical examination in 1926 showed that the spleen was palpable 2 cm. below the left costal margin. Otherwise, the physical examination was normal. The red-cell count was 3,900,000, the hemoglobin 83 per cent (Sahl) or 12.95 gm. per 100 cc., the white-cell count 12,000, with many immature white blood cells. The reticulocytes were 1.5 per cent and the fragility was normal. The white-cell count rose steadily to 40,000, with many myelocytes. The red-cell count rose coincidentally to 4,500,000, and the hemoglobin to 100 per cent (Sahl) or 15.6 gm. per 100 cc.

For the next five years the patient was lost track of, but during this time the spleen gradually increased in size. He was admitted to the hospital on September 12, 1932. The physical examination was normal except that the spleen descended 12 cm. below the costal margin. The red-cell count was 4,500,000, the hemoglobin 80 per cent (Sahl) or 12.48 gm. per 100 cc., and the white-cell count 15,000, with 70 per cent polymorphonuclears, 5 per cent metamyelocytes, 1 per cent myelocytes, 1 per cent stem cells, 3 per cent monocytes and 20 per cent lymphocytes. The hematocrit reading was 42.2 per cent, the mean corpuscular volume 93.8 cu microns, the mean corpuscular hemoglobin 27.7 micro-microgm and the mean corpuscular hemoglobin concentration 29.6 per cent. A fragility test showed that

*For the report of this case we are indebted to Dr. Arthur W. Marsh of Worcester, Massachusetts.

hemolysis began at 0.56 and was complete at 0.30 The icteric index was 9

On October 28 splenectomy was performed. The spleen weighed 745 gm. Microscopically there were focal collections of stem cells and myelocytes. Numerous foci of red-cell formation were present. The number of megakaryocytes was considerable. The Malpighian corpuscles were well preserved. Lymphocytes and plasma cells were scattered through the pulp.

The patient's condition remained good, but the red-cell count fell to 3,000,000 and the white-cell count rose to 70,000 on November 20, with 80 per cent polymorphonuclears, 7 per cent metamyelocytes, 3 per cent myelocytes and 10 per cent lymphocytes. The platelets were normal. An occasional nucleated red cell was seen. The patient's strength gradually failed and he died of bronchopneumonia on January 11 1933. No autopsy was obtained. It is unfortunate that in this case bone-marrow biopsy was unsatisfactory.

CASE 9 (No. 824,534) D. W., a 64-year-old woman, was admitted to the hospital on July 2, 1931 complaining of weakness of 4 months duration. Two years previously she had had a severe attack of weakness, and at this time it had been noted that the spleen was enlarged.

Physical examination was essentially normal, except for a spleen which extended 7 cm. below the costal margin. The red-cell count was 3,830,000 the hemoglobin 71 per cent (Sahli) or 11.08 gm. per 100 cc., and the white-cell count 11,900 with 17 per cent reticulocytes. No record of a differential count was made, but it was noted that many immature granulocytes were present. There was no free hydrochloric acid in the gastric juice. A diagnosis of myelogenous leukemia was made and the patient was put on Fowler's solution by mouth. She left the hospital however and was not seen again until January 31 1935 when she was readmitted for increasing weakness and nervousness.

Physical examination at that time revealed a hard nontender spleen extending to the level of the umbilicus. Otherwise the physical examination was normal. The red-cell count was 3,060,000 and the hemoglobin 57 per cent (Sahli) or 8.89 gm. per 100 cc. The white-cell count was 17,000 with 65 per cent polymorphonuclears, 2 per cent metamyelocytes, 17 per cent myelocytes, 12 per cent lymphocytes, 1 per cent eosinophils and 2 per cent basophils.

The patient was given 400 r to the spleen. Five weeks later the white-cell count had risen to 40,000.

She was readmitted on March 5 1934. At this time the spleen had increased still further in size, now reaching to the iliac crest, and the liver was 5 cm. below the costal margin. The red-cell count was 3,940,000 the hemoglobin 68 per cent (Sahli) or 10.61 gm. per 100 cc., and the white-cell count 28,600 with 13 per cent polymorphonuclears, 41 per cent young polymorphonuclears, 6 per cent myelocytes, 6 per cent promyelocytes, 5 per cent stem cells, 4 per cent basophilic myelocytes, 4 per cent basophils, 1 per cent monocytes and 11 per cent lymphocytes.

The final admission was on May 28 1936. The patient had lost much weight and was somewhat dyspneic. There were signs of bronchopneumonia at the bases of both lungs. The liver and spleen were as before. The temperature was 100.4 F., the pulse 100 and the respirations 30.

The red-cell count was 2,500,000 the hemoglobin 43 per cent (Sahli) or 6.71 gm. per 100 cc. and the white-cell count 36,000 with 25 per cent polymorphonuclears, 12 per cent lymphocytes, 10 per cent monocytes, 48 per cent myelocytes 2 per cent basophilic myelocytes and 3

per cent stem cells. The patient died the day of entrance.

Autopsy (A 36311) showed lobar pneumonia splenomegaly hepatomegaly with hemosiderous chelicitis and osteosclerosis of the vertebral and sternal marrow. The spleen weighed 1570 gm. The liver weighed 2480 gm. The lumbar and sternal marrow were pinkish gray and hard. The tibial and femoral marrow were yellowish white. Microscopically the spleen showed a moderate degree of diffuse fibrosis. Many focal collections of stem cells myelocytes and adult granulocytes were present. There was no evidence of red-cell formation, nor were any immature forms of this series noted. Megakaryocytes were numerous. The Malpighian corpuscles were smaller than normal, and many contained a few stem cells and megakaryocytes. Hemosiderin-filled macrophages were present in large numbers in the pulp. The sinusoids of the liver contained numerous stem cells, immature granulocytes and a considerable number of megakaryocytes. No evidence of red-cell formation was present, nor were any immature red cells seen. Large amounts of hemosiderin occurred in the liver cells, the Kupffer cells, and in macrophages in the portal areas. The tracheo-bronchial lymph nodes contained some myelocytes and polymorphonuclear leukocytes and also some megakaryocytes, but no immature red cells. There was much hemosiderin in the stromal fibroblasts and the endothelial cells of the sinusoids. The sternal bone marrow showed an increased number of bony trabeculae and areas of connective tissue. Large numbers of fat cells were present. There were foci of the granulocyte series with normal maturation. No evidence of red-cell formation was present. Megakaryocytes were fairly numerous. Large amounts of hemosiderin were present. The vertebral and rib marrow presented essentially the same picture. The femoral and tibial marrow contained much fat tissue and a few myelocytes, polymorphonuclear leukocytes, lymphocytes and macrophages.

CASE 10 (H. 39 1280) L. B. a 52-year-old man, was admitted to the hospital on October 16 1939 with a chief complaint of abdominal distress. His past and family histories were irrelevant, except that in recent years he had suffered a good deal from "rheumatism" of the knees and ankles. In February 1938 he noticed that he was losing weight and that he tired easily. Three months later he began to have dyspnea on exertion. At about the same time he noted vague abdominal distress. His abdomen gradually became distended and in July 1939 he noted a hard, nontender mass in the left upper quadrant. At this time he visited an outside hospital where the red-cell count was found to be 7,590,000 the hemoglobin 90 per cent (Sahli) or 14.0 gm. per 100 cc. and the white-cell count 14,750. The differential count was essentially normal. The spleen at that time was grossly enlarged, extending to the midline and to the iliac crest. Otherwise the physical examination was normal.

On entry to the hospital in October 1939 physical examination disclosed a hard smooth spleen extending to the right of the midline and into the false pelvis. The liver was palpable 3 cm. beneath the costal margin. There was evidence of considerable recent weight loss. The red-cell count was 4,800,000 and the white-cell count 14,500 with 37 per cent polymorphonuclear neutrophils 9 per cent young polymorphonuclears 4 per cent metamyelocytes, 13 per cent myelocytes 3 per cent stem cells, 13 per cent monocytes, 10 per cent lymphocytes, 3 per cent basophils, 1 per cent eosinophils and 7 per cent of abnormal cells closely resembling megakaryocytes. A rare normoblast was

seen Two weeks later the hematocrit reading was 29 per cent, the mean corpuscular volume 61 cu microns, the mean corpuscular hemoglobin concentration 34 per cent and the mean corpuscular hemoglobin 23.7 micro-micromg. The red cell diameter was 6.04 microns. Fragility tests showed that there was a moderate increase of the red cells to hemolysis, which began at 0.52 and was complete at 0.32.

A biopsy (S-39-3327) of the sternal marrow showed very extensive fibrosis, but here and there were scattered

cells of the hematopoietic series. The marrow (S-39-3432) from the mid tibia was largely fatty, but here and there areas of fibrosis occurred, containing small collections of immature blood cells of all types. Young blood cells were not seen in the fatty areas. A specimen (S-39-3422) removed at splenic puncture showed marked fibrosis, large numbers of megakaryocytes and many nucleated red cells, normoblasts, myelocytes and stem cells. A definite diagnosis of agnogenic myeloid metaplasia was made.

PENTOTHAL SODIUM ANESTHESIA FOR ENCEPHALOGRAPHY*

MORRIS J. NICHOLSON, M.D.,† AND LINCOLN F. SISE, M.D.‡

BOSTON

ENCEPHALOGRAPHY, when first described by Dandy¹ (1919), was intended as an aid in the diagnosis of hydrocephalus and brain tumor. The introduction of air through the lumbar route was little utilized until 1921, when it was re-introduced and its importance emphasized by Bingle and Wideroe.² Since then its use has been extended to the investigation of practically every disease within the cranial cavity, and it has become an indispensable adjunct to neurological diagnosis.

Encephalography can be one of the most drastic diagnostic procedures patients have to undergo, serious symptoms and occasionally death can occur, and in fact have occurred, during this procedure and after its completion. When encephalography is done under local anesthesia after preliminary sedation "the usual symptoms in the order of their appearance are headache, nausea, vomiting, pallor, perspiration, chilliness, drowsiness, restlessness, poor pulse."³ We have adopted the use of Pentothal Sodium intravenously to produce anesthesia in patients subjected to encephalography in an attempt to avoid these immediate reactions. Some clinics have used the general anesthetics, ether and ethyl chloride, for the same purpose. Solomon and Epstein⁴ (1932) recommended the use of nonvolatile anesthetics, pentobarbital, Amytal or Avertin, and reported good results with the intravenous injection of 0.3 to 0.5 gm. of pentobarbital-sodium.

In our series of 266 encephalograms from 1935 to 1938 inclusive, Pentothal Sodium (sodium ethyl-methylbutylthiobarbiturate) was used as an intravenous anesthetic in 177 cases and Evipal Soluble (sodium salt of N-methylcyclo-hexenyl-methyl-barbituric acid) in 5. Of the remaining 84

cases, which represent a transition period in 1935 and the early part of 1936, before intravenous anesthesia had been fully accepted as a method of choice, encephalography was done in 28 cases under local infiltration anesthesia, in 11 under Avertin plus local infiltration, in 30 under Avertin, in 6 under Avertin and Vinyl Ether, in 4 under Vinyl Ether and in 5 under open ether. There has been no death in this series.

With Pentothal Sodium intravenous anesthesia, the one-hour to two-hour period of postencephalographic somnolence is very helpful to the patient, as it is during this period that the headaches or dizziness are most severe. On reviewing the records of those patients who had intravenous Pentothal Sodium anesthesia and subarachnoid oxygen insufflation, we found that the average duration of the postencephalographic headache was twenty-four hours. A few of the patients had no headache, while others complained of it for two to three days and, rarely, some had it for five days. Nausea and vomiting when they occurred after encephalography were confined to the first six or eight hours.

DOSAGE

The only reliable guide to dosage is the physiologic response of the individual patient. Our experience has shown that the earlier notion of predetermining dosage from body weight may be dangerous. The very old, debilitated patient requires less, while the young, robust, healthy, muscular individual requires more. Patients who have formerly taken daily doses of the barbiturates, such as luminal, for control of convulsions seem to require more because of a tolerance they have acquired for this group of drugs. The average dose of Pentothal Sodium in our series was

*Department of Anesthesia, the Lahey Clinic.

†Anesthetist, Lahey Clinic.

‡Senior anesthetist, Lahey Clinic.

0.85 gm., and this provided anesthesia for the introduction of air and taking of roentgenograms, which together took thirty or thirty five minutes. The minimum dose was 0.3 gm., and the maximum 2.0 gm.

PREMEDICATION

In most cases atropine sulfate, 1/150 gr., was administered subcutaneously one hour before operation, as this medication decreased the formation of mucus and seemed to decrease the frequency of laryngeal and bronchiolar spasm. A few of the patients received morphine sulfate 1/6 gr., and atropine sulfate, 1/150 gr., subcutaneously and pentobarbital sodium 1 1/2 gr., orally one hour before operation, but there was no apparent advantage from this combination of premedicants.

ADMINISTRATION

Close adherence to a definite precautionary routine before the anesthesia is started will prove valuable. One should test intravenous apparatus to be sure it functions properly, obtain the necessary saline solution from a sterile labeled bottle or flask, have airways within reach of the anesthetist and most important of all, have a gas machine at hand so that in case of emergency oxygen may be administered under pressure.

The patient is seated near one end of the x-ray table with his legs hanging over the side and his head resting on the shoulder of an assistant so that his face is toward the anesthetist as shown in Figure 1.⁵ This is important, as the anesthetist can more readily observe respiration and color, and insert airways or administer oxygen if the patient's face is toward him. Usually the median basilic or the median cephalic vein in the left antecubital space is selected for the site of injection. The solution strength now used is 5 per cent in saline. The 10 per cent solution originally employed was discontinued because it occasionally caused slough or local reaction when accidentally injected into the tissues outside the vein.

The 5 per cent solution is aspirated into a 20-cc. syringe, preferably with an eccentric tip, to which is attached a needle of the anesthetist's preference. One of us (L. F. S.) has employed to advantage a piece of rubber tubing to connect the syringe and needle in giving intravenous agents. The rubber tubing is approximately 30 cm. long of fairly small bore and thick walled with a stopcock and glass adapter at one end for the needle, and at the other end a metal adapter into which the syringe tip fits. The syringe is filled with the

solution, the tubing connected, a needle attached to the glass adapter and the stopcock turned off. After proper preparation of the selected area, the tourniquet is applied to the arm, venepuncture made and the stopcock opened. As soon as the blood appears in the glass adapter the tourniquet is released and the needle strapped into place with adhesive, the syringe may also be strapped to the patient's arm or simply held by the anesthetist. This flexible connection between the syringe and needle has helped to prevent the needle from being pushed through the posterior wall of the

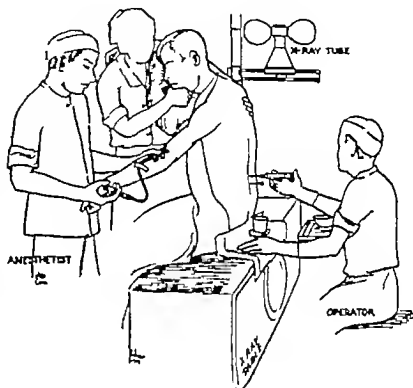

FIGURE 1

vein, as so often occurred with the syringe and needle rigidly connected, when the patient was placed on the table for taking roentgenograms.

Routine use of either a nasal or oral airway is preferred by some, while others use them only when respiratory obstruction is observed. A cotton wisp fastened to the patient's upper lip may be used as an aid in determining the character of respiration⁶ or the anesthetist may listen to the respiratory exchange for any obstruction that may occur.

Injection of the Pentothal Sodium solution is started by the fractional method, and the patient is instructed to count aloud. Initially 3 to 4 cc. is slowly injected in approximately fifteen seconds and after a brief pause to give the solution time to circulate in the blood stream, and permit any individual idiosyncrasy to become manifest before a potentially toxic dose has been administered, another small injection is made. With very young or aged and debilitated patients the initial injection should be smaller in amount and the rate of

administration undertaken slowly and cautiously, always observing the patient's respiration

These small, carefully administered injections are continued until impairment of speech, depressed respirations, loss of conjunctival reflexes and gradual relaxation of the patient mark the onset of anesthesia. Respirations are normal during light anesthesia and become increasingly shallow as anesthesia deepens. While the spinal puncture is being made the patient usually requires an additional small dose of the solution to overcome the painful stimulation.

With the use of the slow, intermittent injections separated by safety pauses, and the maintenance of a clear airway, little difficulty from the anesthetic can be expected. Rarely hiccups will be disturbing, but they can usually be controlled by increasing the depth of anesthesia. On a few occasions patients have shown respiratory depression and anoxemia, which we attribute to overdosage due to too rapid injection. This emergency is handled by oxygen inhalation under pressure or artificial respiration. Respiration can occasionally be started when the patient is still in the sitting position by gentle intermittent pressure over the short ribs.

After the spinal fluid has been replaced by the injected gas the patient is placed in the supine position on the x-ray table and the anteroposterior roentgenograms are taken. Before turning the patient over for the posteroanterior and lateral stereoroentgenograms a final small injection is made, this will generally keep the patient quiet for remaining roentgenograms.

ADVANTAGES, DISADVANTAGES AND CONTRAINDICATIONS

The advantages of intravenous Pentothal Sodium anesthesia are as follows. It provides the neurosurgeon with adequate anesthesia for lumbar puncture, air injection and roentgenography, as the patient is quiet and in good condition throughout the procedure, it overcomes the undesirable reactions formerly seen when encephalography was done under local anesthesia—headaches, nausea, vomiting, pallor, cyanosis, perspiration, chilliness, restlessness and poor pulse, it eliminates the danger of fire or explosion present when inflammable agents such as ether or ethyl chloride are used in the x-ray room⁷, it provides rapid, smooth and pleasant induction for anesthetizing patients in the

sitting position, and it eliminates the possibility of psychic shock.

The disadvantages are these. There may be difficulty in making the injection in certain obese individuals whose veins are small and deeply situated, there is possibility of local reaction if large amounts of the solution are injected in the tissues outside the vein.

Pentothal Sodium anesthesia, given intravenously, is contraindicated in children under seven or eight years of age, since venepuncture is sometimes difficult and maintenance of an even plane of anesthesia is almost impossible, because the patients pass so quickly and unpredictably from one stage of anesthesia to another with the administration of small amounts of the drug, in hepatic insufficiency, jaundice and severe renal disease, as detoxication and urinary elimination are impaired, in patients with increased intracranial pressure with possible medullary compression, because the respiratory center is already embarrassed and the addition of more respiratory depression by Pentothal Sodium may prove fatal, and in patients receiving treatment with sulfanilamide. As the work of Adriani⁸ suggests, this combination of sulfanilamide and barbiturate may be unwise.

SUMMARY

The development of the barbiturates that are both transient and effective in their action has given us a satisfactory intravenous anesthesia for encephalography. A series of cases is briefly presented, giving a method of administering Pentothal Sodium for intravenous anesthesia during encephalography, and the management of complications that may occur. The advantages of this type of anesthesia and its disadvantages and contraindications are also presented.

NURSING, NURSES AND DOCTORS*

STEPHEN RUSHMORE M.D.

BOSTON

IN NURSING there are many serious problems of caring for the sick, of education, of administration, of adjustment to a rapidly changing order so perplexing that one must face the question of what it is that changes and what it is, if anything, that does not change. In working out the solution of these problems the spirit of controversy is to be avoided as contributing little illumination and it is necessary to have wisdom, which includes vision and imagination, insight and creative capacity, endurance and patience. This means, when one has a vision of a goal, of one's ideal, that there shall be no undue haste in seeking its realization. Short cuts are sometimes useful but often dangerous, and it is a false doctrine that the goal can be reached without paying attention to the path taken in pursuing it. The way a thing is done will often determine which one of several possible goals is to be attained.

In entering upon a field of controversy, only the scientific spirit can be relied upon as a guide. This means not merely a willingness or even a desire to consider the facts, but a determination to consider all the facts in the case. In one of his essays, William James, with great insight and a keen sense of humor, refers to the "fluidity of the facts," by which he means, as can be judged by what he said elsewhere about stubborn and irreducible facts, that it is opinions about facts that have this fluidity. It is very difficult to look at all the facts at one time, difficult physically and mentally, because really only one thing at a time can be seen. However quickly the eyes are shifted, at the risk of strabismus, attention to one thing means lack of attention to something else which may also be of vital importance. Thus it is very difficult to see things in proper perspective, difficult but necessary.

As one looks over the whole field of the healing art and sees the multitude of efforts that must be put forth by many kinds of persons, by many groups of individuals, two groups stand out as different from all the others because they come into direct contact with the sick, namely the physician, who has the prime responsibility, and the nurse, who has the secondary responsibility.

Here are all the persons directly involved in the care of a case of serious illness: the patient,

the doctor, the nurse. The hospital superintendent administers merely so that the doctor and the nurse can do their work under better conditions, the medical school is for the education of the doctor, the nursing school for the education of the nurse, the laboratory workers, the technicians, the pharmacists, all help the doctor so that he can help the patient. It is this direct care of the patient that marks off the work of the nurse as different from that of all the other assistants to the physician.

Nursing may be regarded from another point of view. What are the things to be done in nursing? Into what parts can the whole field be divided? There are multitudinous needs which do not require enumeration now, but a practical question is: How many kinds of nurses are required to meet these needs? One answer is, as many kinds of nurses as there are needs. These speculations suggest remoteness from the solid earth of actual practice, for one nurse may perform many kinds of service, meeting thereby as many needs, and a pertinent question is: What is this discussion of kinds of nurses about anyhow?

The full answer would take too long a time to be given now, but a partial answer is given by the dollars and cents involved, by practical economics. In general, people are going to buy such nursing service as they think they need. If they need only a little nursing skill and that is available, they will buy it, if they need much and can get it, they will buy that. But if a little will fill their need, they are not going to pay for something they do not need and cannot use.

On the basis of need of the patient, several levels of nursing service are demanded and will be supplied, and if some classification of nurses is thought desirable, there are two groups, the more highly skilled and the less highly skilled. But such distinction is rather arbitrary as a basis for classification and presents no clear-cut differentiation. In the actual practice of nursing, the nurse does what the doctor directs her to do, according to his idea of the skill of the individual, and not according to her classification.

There is a further question as to how much work there is to be done by these two groups respectively, and the kind of work and the conditions under which it is to be done. Broadly speak-

*An address given at the graduating exercises of the School for Attendant Nurses, Household Nursing Association, Boston, November 23, 1919.

ing, the more highly skilled worker is in the general hospital dealing with acute illness, and the less highly skilled worker is out of the general hospital and deals with chronic illness, or acute illness when the convalescence has begun. There are, to be sure, acute cases at home and chronic cases in hospitals, very many of them, but in a general way the distinction which has been made is sound. It is probably true that the field for the less highly skilled worker is larger and the opportunities, in this sense, are greater, but they are less dramatic and less spectacular.

No use here has yet been made of a specific designation for either of the two kinds of workers in order that any possible prejudice from terms already employed might be avoided, for it is basic facts rather than superficial designations that are important. The basic fact is that one group is more highly trained and the other group is less highly trained, and if one is called the nurse and the other the attendant, there can be no serious objection. Both are in substance and in practical activity workers in the field of nursing by direct ministrations to the needs of sick persons; both are actually nurses.

Reference has been made to the problems connected with these two groups of workers as of similar magnitude in the sense of the number of persons needing the service and the number of persons needed to render the service. This introduces another problem, namely, the need, in a field so extensive and so important for the well-being of the public that there should be some control by the state of all persons who offer themselves for this service. Protection is needed against incompetence, whether due to lack of knowledge or lack of skill or lack of moral stamina. Should not every worker in the field of nursing be licensed by the state as qualified to undertake such duties and responsibilities?

An immediate and natural answer to this question is "Yes, of course they should all be licensed. It is terrifying to think of the harm that might be done by incompetent nurses." This answer has been given by some persons who, however sincere and earnest and unselfish, have not, it appears, thought out to all the practical details the implications of what they propose to do. Some of these details will be noted later.

The next very practical question is: How shall each group be prepared for their work, how shall they be trained, or, better, how shall they be educated? The word "education" in this connection needs no justification, for if this ex-

perience in the school of nursing is looked upon as mere training, there is failure to recognize that the candidates are human beings, preparing themselves for what may be their lifework.

It is clear that considerable time and effort have been directed, in the past twenty-five years, to determining how the more highly skilled worker should be educated, and while the system is by no means perfect, a good, workable and fairly adequate scheme has been devised. But it is a matter for surprise and deep concern that so little attention has been given to the education of the less highly skilled worker. This education of the attendant is in the very early stage of an experiment, and while the school which is carried on by the Household Nursing Association represents a fine piece of work, it has not received in Massachusetts or in other states the enthusiastic imitation that the project deserves. It is a fact that while there has been some talk in the past twenty-five years among persons interested in nursing education, there has been very little done for the attendant, and in some quarters there has been of late an unwillingness even to talk about these problems.

It is because there is no generally accepted body of ideas about education of attendants, incarnate in effective institutions, that the highly experimental stage should be continued for some time longer, until there can be crystallized a reasonable procedure, with a sound experimental basis. What is required now is freedom to experiment, and during the period of experimentation, it may be wise for the state to assist by licensing, on the basis of certain qualifications, persons who desire legal recognition. Licensing gives the attendant the recognition and the status that are appropriate, but until this experiment is distinctly farther along in its development, it would be a serious mistake to have compulsory registration of all who render nursing service. Of prime importance in the working out of a problem as complicated as this, and one which has so many aspects which need consideration, is patience. It is folly to secure legislation of which the consequences have not been thought through and realized clearly. Freedom to experiment in educational procedures is necessary for progress, yet it may be lost with the introduction of such compulsory requirements as have appeared in some drafts of proposed legislation.

The argument for compulsory registration is the protection of the public. But if one listens to the accounts of possible suffering from incompe-

tent nursing as set forth by advocates of compulsory registration, and compares those accounts with what one actually finds, one may well be distressed, yet the actuality does not seem to be so bad as it is represented, and nothing is said of incompetence among registered nurses. Why is the situation not so bad as some persons say it should be without compulsory registration? Very briefly, it is because the chief responsibility for the care of the sick is on the physicians, and it is they who have the responsibility for poor nursing and for good nursing. If they insist on good nursing for their patients, they can usually get it. If they are satisfied with poor nursing the patients suffer. Nurses do not realize with sufficient clearness that nursing can never rise above the level of medicine, and that in the medical profession they owe much, but not all, of what they have been able to accomplish.

What is the proper relation of the attendant to the nurse and of the nurse to the attendant? This cannot be gone into in detail, but one of the basic facts is that both justify their existence by the adequacy with which they render nursing service to sick persons. Both are rendering necessary services for which there will be a permanent need in society. In the final analysis, the relations will be determined by the reciprocal respect, on the part of each group for what the other group is doing.

There is another problem which involves basic issues. If it is not solved properly the system that it supports breaks down. What is the relation of the nurse to the doctor? Some of the things that the nurse may do are part of the practice of medicine. This is true whether she is or is not registered. But she is permitted to do them because she is caring for the sick under the direction and supervision of the physician. If she gives nursing care to a sick person, not in emergency and not under the implicit or explicit direction of a physician she is acting improperly. Now, the basic relation between doctor and nurse has unavoidable implications which some persons are not willing to acknowledge. The implications are not only a responsibility of the physician for what the nurse does in practice, to which reference has been made, but also a responsibility for participating in

the education of the nurse and a responsibility for participating in the determination of her qualifications for the practice of nursing. It is true that some physicians are not willing to accept these offices, but that does not lessen the duty of the medical profession. Neither does it justify the claim that nurses alone should control the education of nurses, or that nurses alone should carry the responsibility for determining the qualifications of the nurse, who is to work only under the direction of the physician. In the field of the healing art, the nurse, whether registered or unregistered, is a subsidiary worker, and it is not likely that this relation will change in this generation. It is the part of wisdom to recognize this fact, and to make plans accordingly.

The final question concerns the status of nursing. Is it a profession? What is a profession? It was formerly easy to answer this question: there were three professions, theology, law and medicine. Now there are many others, and what a change has taken place in medicine itself! It was at one time deemed beneath the dignity of the physician to work with his hands, so the hand worker or surgeon, from which comes the word surgeon, was a barber-surgeon. In the Oath of Hippocrates are these words: "I will not cut persons laboring under the stone, but will leave this to be done by men who are practitioners of this work." Just as medicine has grown to include surgery and has raised it to a professional level, so many callings once thought lowly have taken on a professional tinge. Even business, which had its origin in barter, a word which has apparently the same origin as barratry, a form of cheating, some would raise to the professional level.

The essential distinction of the profession is the spirit in which the worker does his work. The work of the nurse is, in part at least, ministering directly to the needs of sick and suffering human beings, and if they believe in the dignity and worth of humanity even if they do not see very clearly what it is that gives that worth, and if, working for the benefit of their patients, they respect the patients and themselves, they will be able to live their own lives in the spirit of a profession.

570 Commonwealth Avenue

REPORT ON MEDICAL PROGRESS

HEMATOLOGY*

WILLIAM DAMESHEK, M D †

BOSTON

DURING the year 1939, most of the hematological advance centered on physiological rather than morphological principles. Whereas until recent years there was danger that preoccupation with morphology might result in a "dead" subject, there has recently been evidenced, at least in some quarters, a complete turnabout from morphology. The latter nevertheless has its place and its study need not be neglected, even though "dynamic" hematology has proved its pre-eminence.

During 1939, much was learned about hematological methods in diagnosis, motion-picture differentiation of the lymphoblast from the myeloblast, hematologic reactions to drugs, the experimental production of pernicious-anemia-like disease in animals, the gastric mucosa in pernicious anemia, the various events in iron metabolism, the pathogenesis of the hemolytic anemias, the treatment of polycythemia, and vitamin K and prothrombin.

BONE-MARROW BIOPSY

Although a number of observers regard biopsy of marrow by sternal puncture as practically a routine measure in the careful study of a hematologic case, there are others who maintain either that the procedure has no value or that its value is limited. As with many of the diagnostic developments in medicine, it is likely that widespread knowledge of the need for sternal puncture will become manifest only with the passing of time. One is thoroughly accustomed nowadays in the working out of a hematological problem to do a "complete" blood, whereas not so many years ago only a hemoglobin determination was thought essential. The hematocrit reading and the various indices, such as the mean corpuscular volume and the mean cell diameter, have all come to the forefront in recent years, and have proved of great value chiefly in appreciation of the pathologic physiology of a given hematological problem. Biopsy of the marrow by means of the sternal

puncture is only slightly more difficult than venepuncture, and it gives much information regarding abnormal physiology. Regardless of possible diagnostic aid, its educational value alone in making the physician think in terms of bone marrow disease is great. Too often, the blood is considered as a fixed sort of fluid containing certain types of cells. In reality, it is simply a circulating "road way" with cells coming from the blood-forming organs on their way to certain tissues. At a given moment, the circulating blood may improperly reflect conditions in the marrow, the chief blood-forming organ, for a number of different conditions may present an identical blood picture. This is particularly true when pancytopenia is present—that is, a reduction in all the cells of the blood. Pancytopenia may be due to aplasia of the marrow, leukemic hyperplasia, Gaucher's disease, metastatic cancer, particularly of the sarcoma variety, severe infectious states, "spleen-liver" syndromes and certain deficiency states. Many of the diagnostic puzzles in hematology present pancytopenia, the remainder of the cases have, without too much attention to diagnosis, responded to the administration of liver extract, iron or both. It is therefore in the cases with anemia, leukopenia and thrombocytopenia that the sternal puncture is clearly indicated and is often of considerable diagnostic aid.

The technic of sternal puncture is simple, requiring novocainization of a small area in the midsternum in the region of the fourth interspace, and the insertion of an abbreviated lumbar puncture needle or a special sternal puncture needle† until a sensation of "give" is felt. In elderly people, the needle is readily inserted through the bony structure of the anterior lamella, in the young and middle-aged a certain amount of controlled pressure is required. Vogel and Bassett¹ recommend a 12-mm 18-gauge needle for children over one year of age and a 6-mm 20-gauge needle for infants under one year. They use no anesthesia. A small amount of marrow, never more than 1 cc, is aspirated with a 5-cc or 10-cc dry syringe. Inspection of the material in gross

*From the Joseph H. Pratt Diagnostic Hospital, the Blood Clinic of the Boston Dispensary and Tufts College Medical School.

†Assistant professor of medicine, Tufts College Medical School; instructor in medicine, Courses for Graduates, Harvard Medical School, physician and chief of Blood Clinic, Boston Dispensary.

‡The author uses the Becton-Dickinson sternal puncture needle.

as it is aspirated and placed on slides often gives some idea as to the degree of hyperplasia, hypoplasia or leukemic infiltration. Smears are made on slides and stained either with Wright's stain or with Giemsa's. With this method beautiful preparations usually are obtained, by means of which careful studies of the various types of nucleated red cells, white cells and megakaryocytes may be made. Sections may also be prepared by collecting some of the marrow material on filter paper, placing it in Zenker or Zenker formol fixative and later staining it with eosin and methylene blue. Careful and long-continued practice with bone marrow preparations should familiarize the observer with the various normal and abnormal cells and their relations to each other. The trephine method of biopsy which I formerly advocated is now used only if the puncture preparations are inadequate, or if definite confirmation is required regarding such abnormalities as Gaucher's disease, lymphoma, leukemic proliferation aplasia of the marrow or osteosclerosis. In these conditions, the sternal puncture alone may be misleading or offer no diagnostic aid. An excellent and critical review of the subject of bone marrow biopsy is that of Scott.²

RED BLOOD CELLS

Paternity Tests

The use of blood groups in bastardy cases when the question of paternity is involved is receiving increasing attention. In the states of New York, New Jersey and Wisconsin the use of blood group tests in these cases is mandatory, if an individual refuses, he may be suspected of fraud. The tests can be used only to exclude paternity. By using the four ordinary blood groups (O, A, B and AB) paternity can be excluded in only about one sixth of the cases tested when child, mother and putative father are examined. By utilizing anti M and anti N testing serums (Landsteiner Levine), it is possible to divide all individuals into M, N or MN groups. The use of both the ordinary blood groups and of the M and N factors leads to the exclusion of paternity in 33 to 40 per cent of the cases tested. Provided the serums are correctly prepared and the testing properly done and carefully checked, the results obtained are of definite and absolute value. The subject of blood grouping in the establishment of nonpaternity and in baby mixups has been covered by Wiener,³ Levine⁴ and Davidsohn and Rosenfeld.⁵

The Sedimentation Rate

In tubes in which blood has been prevented from clotting by an anticoagulant, the red cells sediment at a rate dependent to a great extent on certain changes in the serum. Some serums, notably those from patients with infectious diseases or any condition in which there is increased breakdown of tissue, have increased rates, that is, they have the property of causing red cells to sink rapidly. This very rapid settling is due to the formation of large aggregations of rouleaux. When rouleaux formation is for some reason impaired, as in sickle-cell anemia (Bunting⁶), the sedimentation rate is considerably slowed. Cutler, Park and Herr⁷ point out that the effect of serum changes on the sedimentation rate is more important than that of anemia. These authors question the necessity of correcting for anemia. According to Ham and Curtis,⁸ who have made a comprehensive review of the entire problem, the Rourke and Ernestine method is the most accurate. With this method, heparin is used as an anticoagulant, the rate of sedimentation is observed at five minute intervals to obtain the second or true sedimentation phase and a correction for anemia by means of the hematocrit is made. Hambleton and Christianson,⁹ on the other hand, state

Alleged improvements upon the Westergren sedimentation method have been presented which appear theoretically correct, e.g. correction for cell volume, the use of heparin in place of citrate and graphic methods of recording the results. Instead of making the test more valuable, these changes have the reverse effect, either by leading to results of less clinical value, or by making the test more tedious to perform or less clear to interpret without increasing its clinical value. Hence it is recommended that the Westergren method, by reason of its simplicity, reliability and priority, should be adopted as the standard method of performing the sedimentation test.

The sedimentation rate is so nonspecific that one questions the desirability of attempting too great accuracy with the procedure. Furthermore, it is important to realize that the test is by no means infallible; abnormal rates may be obtained in normal individuals, especially in the older age groups, and normal rates are often present even when serious organic disease, such as cancer, is present. The sedimentation rate should be regarded as a single laboratory procedure which, with all the rest of the data, may be of some significance in helping to evaluate a given problem. In the follow-up of such conditions as rheumatic fever, rheumatic heart disease, rheumatoid arthritis and coronary thrombosis the test is apparently

of definite value. As with many other laboratory procedures, its value depends to the greatest extent on the observer's critical judgment

Stiles¹⁰ conducted an interesting comparative study of the value of blood smears and sedimentation rates in "low-grade chronic illness," such as nasal congestion, postnasal discharge, chronic bronchitis, colitis, prostatitis and rheumatic pains. The immature polymorphonuclear cells ("non-filament cells") were increased in practically all these cases and their number returned to normal as the condition improved. More than 80 per cent of the sedimentation rates were abnormal. The blood smear, although a more sensitive indicator of the presence of disease, was found less significant because of this sensitivity. In infectious mononucleosis, even with marked disease present, the sedimentation rate is usually normal.

Stippling of the Red Cells

The clinical significance of punctate basophilia or stippling was studied by Falconer.¹¹ The Jenner-Giemsa stain was used and five thousand erythrocytes were studied in each case. In normal individuals, the "mean punctate basophilia" was 92 per million red cells. In various types of anemia not due to lead, the counts varied from 2000 to 27,000. In 8 workers exposed to lead but free of symptoms, the average stippled count was 2100 per million red cells. Thus stippling, although common in lead poisoning and often diagnostic, is not pathognomonic of the condition, but may occur in various states, particularly when associated with anemia. Absolute diagnoses in questionable cases are made by urinary-excretion studies, spectrographic determinations of the blood and urine and so forth.

Indices

The various devices for estimating the dimensions of the normal and abnormal red cell are by now well known, and are coming into increasingly common usage. These have been popularized by Wintrobe and include mean cell diameter, mean cell volume, mean cell thickness, mean corpuscular hemoglobin concentration and so forth. Of these, the mean corpuscular volume has come into the widest use, superseding to a great extent the more laborious methods of Price-Jones for differentiation of normocytic, macrocytic and microcytic anemias. There is at times, however, an unfortunate tendency to diagnose macrocytic anemia when the mean corpuscular volume is only slightly elevated above the normal range of 84 to 94 cubic microns. In severe anemia, when slight fluctuations in hematocrits and erythrocyte

counts may result in marked changes in the estimated mean cell volume,* a normocytic type of anemia may, because of slight technical differences, be considered macrocytic, that is above 94 cubic microns. Study of the mean cell volume alone, without reference to the mean cell diameter, will occasionally lead to error, especially in the hemolytic anemias. Here it is occasionally of some importance to know whether there is a true macrocytic type of anemia or one in which the red cell diameter is normal but the mean cell volume is greater than normal. A "pseudomacrocytosis" may be associated with a normal red-cell diameter (normocytosis) and an increase in red-cell thickness. This is probably the situation in most of the cases of so-called macrocytic hemolytic anemia.¹²

Kato¹³ has created an ingenious triaxial chart which correlates the color index, volume index and saturation index. By use of this chart, Kato states, it is possible to make "an accurate hematologic classification of all types of anemia, so essential a foundation for rational therapy." The chief value of the various indices, aside from the intellectual diversion they might give, rests in the value they may have in the treatment of anemia. For use in infants and young children, Kato¹⁴ has devised a "combination microhemopipette" which is useful in determination of the hemoglobin, hematocrit reading, sedimentation rate, fragility test and prothrombin time.

WHITE BLOOD CELLS

The function of the *lymphocyte* has for many years eluded numerous investigators. By motion picture studies of supravital preparations of cells which had been grown in tissue cultures, Rich, Lewis and Wintrobe¹⁵ effectively showed that the large cell of acute splenic tumor and of the regional lymphadenopathy of acute infections was an early or large lymphocyte. Enlargement of the spleen or lymph nodes was frequently found to be nonspecific and noninfectious (allergic states, serum sickness). It was suggested that lymphocytes might have something to do with the formation of antibodies to foreign protein. In another study of leukemic blood cells from tissue culture preparations the same workers¹⁶ demonstrated conclusively the very marked physiologic differences between the myeloblast, the lymphoblast and the monocyte-histiocyte. They pointed out the lack of definite information which ordinary supravital preparations may give regarding cellular motility, and the very striking cytologic differences

*With a red-cell count of 1 500 000 and a hematocrit reading of 16, the mean corpuscular volume is 106 cubic microns (macrocytic). Another count just as accurate may show a red-cell count of 1 700 000 and a hematocrit reading of 15, the mean corpuscular volume being 90 cubic microns (normocytic).

seen with the combination of the tissue-culture technic and slow motion cinematography

The cells of *infectious mononucleosis* have been shown by numerous investigations to be abnormal lymphocytes. The word mononucleosis is a relic of the days when lymphocytes and monocytes were indiscriminately grouped together as mononuclear cells. The name of the condition might well be changed to infectious lymphocytosis or benign infectious lymphadenosis. Be that as it may the condition is a very common one and still goes unrecognized in many cases. It is very likely, as stated by Foord and Butt,¹⁷ that only a small proportion of the actual number of cases that occur are properly diagnosed. From the standpoint of differential diagnosis in conditions associated with continued fever, chills and fever, headache with cerebral symptoms, jaundice, abdominal pain (particularly in children), severe sore throat and so forth, the practitioner should be constantly on the alert for the disease. This is particularly true if a college student, a medical student or a nurse contracts some sort of febrile illness. Generalized lymphadenopathy is not always present in some cases there is only localized adenopathy or splenomegaly. The white-cell count may be low normal or high. Owing to enlarged mesenteric lymph nodes, abdominal pain may be present this symptom, associated with a high leukocyte count, may tempt the surgeon to perform an appendectomy. With a low leukocyte count, the possibility of agranulocytosis may be considered. A positive diagnosis can be made in the great majority of cases by careful examination of the stained blood smear, which shows a bizarre type of lymphocytosis with all sorts of queer staining and unusually shaped lymphocytes. The platelets are abundant, and there is no anemia, both of which are important differential points with respect to leukemia. The serum test (heterophil agglutination test) has proved to be very valuable in confirmation of the diagnosis. Positive tests are usually found as early as the fifth day, although the titer may continue to increase during the first ten or fourteen days. The positivity of the test remains, according to Davidsohn¹⁸ who has done some of the outstanding work with the test, for an average of one hundred and nineteen days. Clinical recovery is rapid—a matter usually of two to four weeks, complete hematological recovery occurs in sixty to ninety days, or even longer in some cases, complete serological recovery is generally slowest. In a certain number of the cases (up to 18 per cent according to A. Bernstein¹⁹) the serological tests for syphilis may be positive, becoming negative as the condition improves.

HEMATOLOGIC REACTIONS TO DRUGS

The startling therapeutic effects of sulfanilamide and sulapyridine have at the same time been associated with an increase in the incidence of hematologic reactions. The bone marrow appears to be especially vulnerable to chemicals containing the benzene ring. This vulnerability may manifest itself in the blood as a total effect, with resultant anemia, leukopenia or thrombocytopenia, or in a more selective fashion. Most of the recent investigations have demonstrated that the cyanosis of sulfanilamide administration is due to the development of methemoglobin or sulf hemoglobin. In the work of Harris and Michel,²⁰ it was found that the degree of methemoglobinemia correlated in general with the blood sulfanilamide concentration, although other individual factors were undoubtedly important. It was shown by Harris²¹ that sulfanilamide in the presence of both hemoglobin and animal tissue resulted in methemoglobin formation in vitro. Sulfanilamide incubated with hemoglobin alone failed to cause methemoglobin production. As a rule, one is not concerned with the degree of cyanosis, if this is excessive, however, Campbell and Morgan²² recommend the administration of methylene blue intramuscularly (400 mg.), intravenously (150 mg.) or by mouth (1 gm.).

Agranulocytosis probably represents, at least in many cases, a sensitization phenomenon on the part of the bone marrow leukocytes to a chemical which may have become linked to serum protein. Thus far, a test for the susceptibility of a given individual to the sulfanilamide group of drugs has not been developed. The severest reactions probably occur when the drug is given intermittently, although it is possible, as pointed out by Butt, Hoffman and Soll²³ in their animal experiments with amadopyrine, that large doses given over a long period of time may cause toxic hypoplasia of the marrow with resultant granulocytopenia. Jackson and Tigbe²⁴ analyzed 239 cases of agranulocytosis reported since 1933. In 75 untreated cases the mortality rate was 78 per cent, whereas in 85 cases treated with pentose nucleotides the mortality rate was 35 per cent. The recommendation is made that at least 40 cc. of the latter material be given daily. In the experience of many hematologists scattered throughout the country and personally interviewed, the results with this drug—and with all other measures—in cases of agranulocytosis due to sulfanilamide or one of its derivatives have been disappointing. It would seem that there is no one specific of value in treatment if the bone marrow leukocytes

are not irretrievably damaged, the patient will recover, otherwise the effects of therapy in a given case are very dubious

Leukemoid reactions following sulfanilamide are occasionally seen, and recently an interesting case was observed in which there was first a leukemoid reaction (high white-cell count, myelocytes) followed by a granulocytopenic reaction. At times, one suspects the possibility that acute leukemia itself might have been initiated by the drug. The cases in which acute leukemia follows sulfanilamide administration do not in all probability indicate more than a coincidental relation, although at times a possible causal relation must be suspected. Thrombocytopenic purpura and complete aplastic anemia are rare with sulfanilamide. About fifty cases of the former condition have, however, been reported following the use of the sedative Sedor-mid.

PERNICIOUS ANEMIA

Wintrobe, Samter and Lisco²⁵ have produced a close analogue of pernicious anemia in young suckling pigs by the use of a diet deficient in the various factors of the B₂ complex. The feeding of yeast was sufficient to prevent the anemia, but in the absence of this substance a macrocytic anemia hematologically comparable to that seen in pernicious anemia was observed, together with neurologic lesions and a hyperplastic bone marrow. No response occurred when nicotinic acid, riboflavin or vitamin B₁ was administered, but reticulocytosis and marked improvement in the anemia occurred when yeast was given. These experiments are confirmatory of the well-known theory that pernicious anemia is a deficiency disease, perhaps concerned with a long-standing dietary deficiency, either as such or conditioned by an abnormality of the gastrointestinal tract. Alsted²⁶ reports a clinical case of "exogenous pernicious anemia" which developed as the result of a totally inadequate diet, although the gastric juice contained free hydrochloric acid, an excellent therapeutic result was obtained without the use of liver extract. Whatever the cause, deficiency in the liver-extract principle results in a peculiar hyperplastic state in the bone marrow. This is characterized by an increase in primitive erythroblasts (erythrogones) and the presence of characteristic megaloblasts and of abnormally shaped metamyelocytes. Israels²⁷ confirms the work of Dameshek and Valentune²⁸ on these points.

The appearance of the gastric mucosa in life was studied by Schindler and Serby²⁹ in 23 patients. All the untreated cases presented superficial gastritis, atrophic gastritis or patchy atrophy.

In 12 cases the condition of the gastric mucosa after treatment was greatly improved. From these observations, it was postulated that two separate disorders might be present in pernicious anemia: a primary disorder of the cells producing the anti-anemic factor, and a gastritis which might or might not heal when the deficiency state is eliminated. The condition of the tongue and that of the gastric mucosa are frequently related. That pernicious anemia is also a hemolytic anemia has recently been stressed by Rhoads and Miller.³⁰ To explain this on a deficiency basis is difficult, unless one postulates, as Rhoads has done, that in the presence of a deficiency state certain toxic processes might become unusually active in hemolysis. In the therapy of the disease, Meulengracht³¹ found that parenteral therapy was too expensive for most Scandinavians and of no greater potency than Pylorin, which is derived from the mucosa in the region of the pylorus. This material, apparently twice as potent, gram for gram, as Ventriculin, was effective in maintaining a normal blood picture and in preventing neurologic involvement. In this country it is possible that we are too free in the use of parenteral therapy and that a certain number of patients would probably do very well on oral therapy alone. At times, this method of administration becomes necessary when the patient develops severe reactions to injected liver extract. If this should eventuate, three courses are open to change from the ordinary swine-liver extract to beef-liver extract*, to desensitize the patient by giving gradually increasing doses, and to give liver, liver extract or gastric extract by mouth. In the presence of neurologic lesions, parenteral therapy must of necessity be continued. It should be noted that even at a normal red-cell level, neurologic lesions may still be present. These may well respond to intensive parenteral therapy. This is particularly true of lesions in the posterior columns. In my hands, highly concentrated and refined liver extracts, which the patients like because of their small bulk, are highly effective, perhaps even more so than are the more dilute, cruder types. This indicates that what the patient with neurologic involvement needs is plenty of liver-extract principle and that other factors, including the vitamin B complex present in the dilute liver extracts, are not ordinarily essential.

IRON DEFICIENCY ANEMIA

A number of investigators have recently pursued various aspects of the problem of iron metab-

*Campolon Liver Extract (Winthrop) or Lederle Beef Liver Extract (obtainable on request) may be used.

olism. Josephs³² found that during the first months of life there was a tendency to a negative iron balance (loss of iron from the body), a positive iron balance was later established. Whereas normally about 60 per cent of the ingested iron was absorbed, a slightly diminished retention of iron was present during infections and in vitamin D deficiency. In anemia, the organic iron of the tissues appeared to be retained, at times it became unavailable for use by the marrow. Inorganic medicinal iron was, however, readily available. An interesting study with "marked" or radioactive iron was made by Hahn, Bale, Lawrence and Whipple³³ in anemic dogs. In the normal dog, iron was absorbed in only negligible amounts, but in the anemic animal it was promptly assimilated, absorption taking place through the mucosa of the small intestine, whence the iron is transported in the plasma. Within a few hours, in the anemic dog, some of the absorbed iron was found in the red cells of the blood. The reticuloendothelial cells of the spleen and marrow took up large quantities of iron, in this manner acting as a reserve store of readily available and utilizable iron. Moore, Minnich and Welch³⁴ present a very interesting group of observations dealing with changes in the serum iron and in the "easily split-off" blood iron. Serial observations during iron therapy gave a dynamic picture of the rapidity of transportation and absorption of ingested iron. The serum-iron absorption curves were higher following ingestion of ferrous than of ferric salts, this was particularly true of the water soluble, highly ionized ferrous salts. Differences in gastric acidity exerted no measurable effect on serum iron absorption curves when inorganic iron was given. Ingested iron is probably acted on by the free hydrochloric acid of the gastric juice, which may dissolve and ionize it. In the duodenum, the ionized iron is probably reduced from the ferric to the ferrous form. Absorption then takes place as ferrous iron, largely in the upper part of the small intestine.

Kennedy³⁵ conducted a study on the incidence of anemia in women of the low income class in Montreal. He found that menstrual loss was of definite importance in the development of anemia, and that the low iron content of the diet necessitated by poverty was often insufficient to keep pace with the demands of menstruation and repeated pregnancies. Bethell, Gardiner and MacKinnon³⁶ studied the influence of iron and the diet on the blood in pregnancy. The basic diet recommended for pregnancy, as formulated by the League of Nations Technical Commission

provides a daily protein intake of approximately 80 gm., including meat, eggs and adequate quantities of vitamins A, B (complex), C and D. Anemic women receiving iron (ferrous sulfate, 15 gr daily) showed much higher hemoglobin and red-cell values than did those not receiving this medication. Patients without anemia did about the same whether or not iron was given.

The chronic primary or idiopathic hypochromic anemia, which is an iron-deficiency state occurring usually in adult women, is for the most part associated with menorrhagia, multiple pregnancies and inadequate iron intake, plus the added and very important factor of an impaired gastric mucosa, as shown by achlorhydria and directly by visual inspection with the gastroscope. Occasional cases of this sort are seen in men but they are extremely rare, and the question of past or occult bleeding from the gastrointestinal tract should be thoroughly investigated. The response to inorganic ferrous iron (ferrous sulfate, 15 gr daily) in these cases is dramatic.

HEMOLYTIC ANEMIAS

Although the diagnosis of acquired hemolytic jaundice or anemia has for some reason gone out of fashion in recent years, there are indications that it might well be revived. A tentative classification of the hemolytic anemias is as follows:

Congenital

Acute ("hemolytic crisis")

Chronic

Acquired

Known cause

Infections (Welch bacillus, malaria and so forth)
chemicals (sulfanilamide and so forth)

Symptomatic (carcinomatosis, Hodgkin's disease, lymphosarcoma, leukemia and so forth)

Idiopathic (with or without hemolysins or auto-agglutinins in the blood serum)

Acute

Subacute

Chronic

Barker³⁷ and Vaughan and Saifi³⁸ emphasize the importance of determinations of the daily fecal urobilinogen output as a measure of the degree of hemoglobin destruction. In hemolytic anemias, including pernicious anemia, the urobilinogen output is greatly increased. The latter is a far more sensitive test than the urinary urobilinogen output, at least as measured by the ordinarily used Wallace-Diamond technic.

An excellent discussion of the spherocyte and its relation to hemolytic anemia is presented by Haden³⁹, the relatively thick spherocyte which is seen in various hemolytic syndromes cannot take

up very much water when placed in hypotonic solutions of sodium chloride, and therefore bursts (complete hemolysis) long before the more normal biconcave disk. Conversely, a very flat cell is more resistant because it can imbibe a large quantity of water before bursting. Heilmeyer⁴⁰ and Schwartz and I¹² disagree with the current conception that the bone marrow is at fault in congenital hemolytic jaundice and produces thick cells or spherocytes. Heilmeyer believes that the spleen is responsible for the spherocytosis. Dameshek and Schwartz have demonstrated that anemia with spherocytosis may be experimentally produced by hemolysins, on this and other grounds, they have evolved the conception that hemolytic anemia of various types may be due to hemolysins of different types acting in various "dosages." Spherocytosis and increased saline fragility may thus be taken simply as indicative of the presence of a hemolytic process. The spherocyte is the forerunner of hemolysis. Because spherocytes are rounder than normal, they have difficulty in piling up in rouleaux in fresh preparations. Examination of fresh preparations of blood may thus be diagnostic of hemolytic anemia, as pointed out by Dameshek.⁴¹ The abnormal rouleaux are short and form very poor aggregates, thus in hemolytic anemias the sedimentation rate is apt to be slow. Vaughan⁴² noted that following splenectomy in congenital hemolytic jaundice the red cells often became normal in size, although they still retained an abnormal fragility. The loss in spherocytosis indicated to Vaughan that the spleen has some effect in altering the shape of the red cell, the persistence of increased fragility might indicate, however, a fault in red-cell formation. She suggests, therefore, that in congenital hemolytic jaundice there may be disturbances in both splenic and bone-marrow function. According to Berghem and Fahraeus,⁴³ the spleen is the "incubator of the body," and within its relatively static confines, the blood cells are acted on by a substance normally present in plasma, namely "lysolecithin." This substance, which may be responsible for normal red-cell destruction, is said to have the capacity to change biconcave red cells to spherocytes and thus to inhibit the sedimentation rate. Singer⁴⁴ has developed a micromethod for testing this normal lysis in the blood, he found no increase in lysolecithin in the blood of cases of hemolytic anemia. Because the spherocytes of congenital hemolytic jaundice can be hemolyzed by lysolecithin in high dilution, whereas spherocytes from other conditions behave like normal erythrocytes, Singer postulates that spherocytes, although morphologically

identical, may be physiologically different. This has been the point of departure for the concept of differential fragility, as proposed by Dameshek, Schwartz and Singer.⁴⁵ By testing the same red cell against different types of lysins, it is possible that different types of spherocytes may be discriminated and that, in this way, clues may be obtained as to the cause of the spherocytosis.

For some reason the diagnosis of acquired hemolytic icterus or anemia has been avoided in recent literature, and has been to a great extent superseded by such terms as Lederer's anemia and macrocytic hemolytic anemia. The eponymic term Lederer's anemia is probably not justified, because the condition was described in case reports by various European writers for many years before Lederer's descriptions in 1925 and 1930. The term macrocytic as applied to these cases is also probably not entirely justified, because the mature red cells in this condition are not macrocytic but either normal in size or microcytic. The macrocytosis is usually more apparent than real, being due to the large number of immature polychromatophilic reticulocytes, which are larger than the normal mature red cells, as well as to increased thickness of the erythrocytes. Watson⁴⁶ uses the term macrocytic hemolytic anemia as synonymous with acquired hemolytic jaundice. In most of his cases there was true macrocytosis, but this was probably due to the fact that cirrhosis of the liver, Hodgkin's disease or leukemia was present. Autoagglutination of the red cells, as occurring in acquired hemolytic jaundice, was stressed by Widal and his collaborators between 1907 and 1914. It has recently been rediscovered and has been reported in a number of cases of acute and macrocytic hemolytic anemia. Antopol, Applebaum and Goldman⁴⁷ report this phenomenon, which may make blood grouping tests difficult, in 2 cases of acute hemolytic anemia following the administration of sulfanilamide.

One of the most dramatic events in medical practice is the effect of splenectomy in a patient seriously ill with the hemolytic crisis of congenital hemolytic icterus or with acute (acquired) hemolytic anemia. Within a few hours after operation, there is usually a remarkable improvement both in the appearance of the patient and in his sense of well-being. Before the operation of splenectomy is decided on, the effect of one to three transfusions of carefully matched citrated blood of the same blood group given slowly may be tried—"bank" blood should not be used. If evidence of hemolysis continues, splenectomy should be performed without further delay. The giving of too

many transfusions may result not only in severe reactions but in overburdening the circulation, too much delay may result in a fatal outcome. The acute hemolytic crisis, whether congenital or acquired, requires careful and intelligent handling, and represents as much of an emergency as a case of diabetic coma.

Of 15 cases recently observed by me, 8 patients made dramatic and sustained recoveries, 5 died shortly after operation, and 2 relapsed. Of the latter, one has died and the other has improved after a second operation in which a dermoid cyst was removed. Andrus and Holman⁴⁸ recommend the injection of 1 cc. of adrenalin just before delivering the spleen. The resultant splenic contraction is said to facilitate the delivery of the organ into the wound, and also expresses some of the excess splenic blood into the general circulation. They report seventeen splenectomies in hemolytic jaundice without an operative death. Thompson⁴⁹ discusses typical and atypical hemolytic anemias and the end results of splenectomy. The results were uniformly good (except in 1 case) in the typical group, but were poor in the atypical group, including cases of acquired hemolytic jaundice.

ATYPICAL HEMOLYTIC ANEMIAS

Sickle-Cell Anemia

Diggs and Bibb⁵⁰ describe the red-cell characteristics in sickle-cell anemia. The percentage of typically sickled cells is not related to the severity of the anemia. 'Mexican hat cells' (Haden and Evans⁵¹) or "target cells" (Barrett⁵²) are common. These cells are shaped like a bull's-eye or target in stained preparations, and are more resistant to hypotonic solutions of salt than are the normal erythrocytes. Arena⁵³ reports 5 cases in children, notable because of the appearance of serious cerebral vascular disturbances. Capillary stasis due to distortion and agglutination of red cells, together with other factors such as fever and infections, probably contribute to the development of arterial thromboses.

Erythroblastic Anemia

Atkinson⁵⁴ points out the various clinical features of Cooley's anemia, usually a disease of young children and ordinarily fatal before puberty. The 2 cases described have been followed for thirteen years. The girl, aged twenty, began to menstruate at sixteen and is asymptomatic; no nucleated red cells have recently been seen. This is apparently a very mild case, which may be more or less "burnt out." The patient's brother, aged seventeen, has had a much more stormy course, perhaps because splenectomy was done at the age

of six. Showers of nucleated red cells have persisted without much change over the years. The treatment has consisted of iron in large doses. The author quotes Caminopetros,⁵⁵ who found that certain relatives of individuals with the disease showed an increased resistance of the red cells to hypotonic solutions of salt; these individuals, Atkinson believed, might be the carriers of the disease. The red cells of Cooley's anemia, unlike those of congenital hemolytic jaundice and like those of sickle-cell anemia, show a decreased fragility.

POLYCYTHEMIA

Rosenthal and Bassen⁵⁶ present an interesting study on the course of polycythemia based on an analysis of 13 cases. The disease may be asymptomatic and discovered accidentally. It may be of many years duration. Extremely high platelet counts were present in about 30 per cent of 75 cases; in these thromboses were common. These authors lay much stress on the evidences of leukoblastic activity and on the possibility that leukemia will eventually develop in many cases. "Spent" polycythemia may be associated with a chlorotic (low hemoglobin) tendency, high platelet or leukocyte counts, or osteosclerosis. Possibly belonging to the latter group of cases are the 2 cases of "leuko-erythroblastic anemia" and myelosclerosis reported by Vaughan and Harrison.⁵⁷ Both their patients had initial polycythemia, but when studied several years later they showed marked splenomegaly, irregular density of the spongiosa of the bones, anemia with leukocytosis, thrombocytosis and nucleated red blood cells, increased saline fragility and fibrosis of the marrow. Miller⁵⁸ reports on the high incidence of coronary artery thrombosis in polycythemia vera as based on 7 cases which came to postmortem examination of these 3 showed the evidences of coronary artery occlusion.

Haden⁵⁹ discusses the red-cell mass in polycythemia with relation to diagnosis and treatment. The red-cell mass is determined from knowledge of the volume per cent of packed red cells (hematocrit reading) and the total blood volume. The red-cell count does not accurately measure the total increase in the mass of red cells within the body since the red cells are apt to be small and hypochromic, whereas the red-cell mass per kilogram is the most sensitive indicator. Haden believes that the treatment of polycythemia should be based on the total red-cell mass. Dameshek, Henstell and Schwartz⁶⁰ have come to similar conclusions, except that they believe that in practice the use of the hematocrit reading for an indication of the total red-cell mass is justifiable. Therapy should be directed to lowering the hematocrit

reading and maintaining it at a normal level (approximately 46 per cent) After the establishment of an iron-deficiency state by repeated venesections (usually two per week for three or four weeks) of 500 cc, continuation of the iron-deficiency state may be maintained by a diet low in iron The red-cell count may rise in three or four months, but so long as the hematocrit reading remains at an essentially normal value, no further treatment is necessary Ordinarily, cases will go along for eight to fifteen months between series of venesections

The use of a low-iron or low-protein diet alone has not been found effective in our cases, but Herzog and Kleiner⁶¹ report striking results in 19 cases with a diet extremely low in animal protein Andersen, Geill and Samuelsen⁶² treated a case of polycythemia with x-rays over the Brunner-gland region of the stomach and duodenum, with an excellent result Their purpose was to diminish secretion in the area in which the intrinsic factor is formed The authors believe that this method is more rational than that of treating the bone marrow with x-rays My experience with x-ray therapy in this disease has been disappointing, furthermore, it seems unwise to expose an individual with essentially normal tissues to x-ray therapy, which might at some future time result in neoplastic proliferation

HEMORRHAGIC STATES

Blood Clotting

Seegers and his co-workers⁶³ at the University of Iowa describe further work in the purification of thrombin The addition of calcium and thromboplastin to a prothrombin solution resulted in a crude thrombin which could be further purified One cubic centimeter of a 1 per cent solution of this purified thrombin was effective in clotting 1 cc of blood in two seconds By the use of a thrombin solution spray, these workers were able to stop the oozing from incised liver, bone and brain tissue Its application to clinical hemorrhagic conditions has thus far been slight, but the further results of these investigators will be well worth watching

The clotting of blood is taken up from another direction by Ferguson and Erickson,⁶⁴ who have studied the action of trypsin This enzyme can clot citrated plasma without added calcium or cephalin Trypsin may be one of a series of thromboplastic enzymes which cause the mobilization of calcium and thromboplastin about prothrombin, with resultant formation of thrombin Ferguson and Erickson have also been able to activate the prothrombin of hemophilic "globulin substance" to normal thrombin, with resultant clotting, by

the addition of pure crystalline thrombin The plasma of individuals with hemophilia may be deficient in thromboplastic enzyme

Hemophilia

In last year's review the studies by Lozner and Taylor⁶⁵ on the coagulation defect in hemophilia were presented At that time their experiments revealed a deficiency in the globulin fraction of the plasma "Globulin substance" prepared from normal human plasma was found to hasten the clotting time for hemophilic blood, both in vitro and in vivo After several injections of this substance, however, a refractory phase occurred so that the clotting time rose to its original level despite continued injections When normal or lyophilized plasma was injected the refractory period was ended, indicating that whole plasma contained a substance that was effective

In a more recent publication, Lozner, Kark and Taylor⁶⁶ state that normal serum from which prothrombin and fibrinogen had been removed was still capable, when injected, of causing a prompt fall in the coagulation time of hemophilic blood, both in vitro and in vivo It was suggested that the loss of effectiveness of the globulin substance might be the presence of a factor in normal plasma which was lost in the acid precipitation of the globulin substance Therefore, globulin was prepared by dialysis by Lozner and Taylor,⁶⁷ and such a preparation of euglobulin was found to resemble normal human plasma in its ability to maintain in hemophilia a reduced level of the blood-coagulation time when injected intravenously every six hours One hopes that in time the results of these investigations will be to produce a substance which when injected periodically into a patient with hemophilia will maintain his blood at a normal coagulation level

Vitamin K

During the last few years, outstanding advances have been made in the troublesome and dangerous hemorrhage of jaundice Quick⁶⁸ deserves great credit for the initiation and development of these studies In obstructive jaundice or biliary fistula, where bile salts do not reach the intestinal tract, poor absorption of fat-soluble vitamins results Rarely, a severe dietary deficiency may lead⁶⁹ to a lowering of the vitamin K content of the body (Kark and Lozner) In the absence of fat soluble vitamin K there is lowering of the plasma prothrombin, with a resultant hemorrhagic tendency The plasma prothrombin level can be sustained by giving vitamin K concentrates and bile salts

by mouth. Blood transfusion is a rather inefficient method of combating the bleeding tendency due to hypoprothrombinemia, as its effect is slight and transient. After a 600-cc. transfusion in one patient, Stewart⁷⁰ found an increase of only 6 per cent of plasma prothrombin.

Rapid progress has been made in the chemistry of vitamin K. A rather large number of compounds with vitamin K activity have been found, and several of these have been identified and synthesized. When oral administration is uncertain because of vomiting or severe diarrhea, a highly purified preparation or one of the recently developed synthetic products may be used. In the synthesis of such preparations, Doisy and his collaborators⁷¹ at St. Louis and Fieser and his co-workers⁷² at Harvard have done outstanding work. Frank Hurvitz and Seligman⁷³ report 2 cases treated with Fieser's synthetic vitamin K. In both cases, a single intravenous injection of the substance resulted in a fall of the prothrombin clotting time to normal within a few hours.

The mechanism by which prothrombin is formed and its dependence on vitamin K are not understood. The liver has been regarded as the site of prothrombin formation because hepatoxins, such as chloroform, cause a plasma prothrombin deficiency, and because some patients believed to have severe liver damage have failed to respond to large amounts of vitamin K and bile salts. In the dog, total hepatectomy causes a rapid fall in plasma prothrombin.

Until recently, the mechanism in the condition known as hemorrhagic disease of the newborn has not been understood. Quick⁷⁴ suggested a prothrombin deficiency. In a study of 20 newborn infants, Waddell and Guerry⁷⁵ showed that the prothrombin clotting times were unusually high between the second and sixth days of life, corresponding to the time at which hemorrhagic disease almost always manifests itself. Administration of vitamin K concentrates orally kept the prothrombin and blood-clotting times normal. Routine use of such therapy in the infant or possibly in the mother late in pregnancy may be the answer to the prophylaxis of many cases of intra cranial hemorrhage during birth and of the occasional fatal bleeding following surgical procedures, such as circumcision early in life.

Owen, Hoffman, Ziffren and Smith,⁷⁶ who with Quick have contributed so much to our knowledge of vitamin K, have also simplified the prothrombin clotting test so that an easy bedside method is now available which correlates well with the more complicated procedures. It should be emphasized

that vitamin K is of no value in the therapy of any hemorrhagic condition except that of prothrombin deficiency. Thus it has no effect whatever in hemophilia, in thrombocytopenic purpura or in any other type of purpura.

Thrombocytopenic Purpura

Very little that is new has been written of thrombocytopenic purpura in the past year. Some new cases of purpura caused by the taking of Sedormid are reported. McGovern and Wright⁷⁷ point out that Sedormid may cause a serious hemorrhagic syndrome. They advise restriction of its sale except on a physician's prescription and caution on the part of the physician in recommending its use. In 1938, a slight sensation was occasioned by the appearance of data purporting to show that splenic extracts from cases of thrombocytopenic purpura resulted in marked reduction in platelets in rabbits. The substance causing this reduction was named "thrombocytopen."⁷⁸ Numerous investigations undertaken in an attempt to confirm this phenomenon have, however, proved uniformly unsuccessful.⁷⁹

TRACY B. MALLORY, M.D., Editor

CASE 26241

PRESENTATION OF CASE

First Admission (July 30 to August 21, 1935)
A twenty-three year-old housewife was admitted to the hospital, complaining of painless swelling of the right neck.

Approximately sixteen months before admission in March, 1934, the patient first noted a constant, non-radiating, dull pain, located in the right side of the neck, below the angle of the jaw, and over an area where there was a palpable, marble sized mass. Within a few weeks the soreness passed away, but the mass persisted, gradually increasing in size. She continued her work and detected little change in her general condition until about nine months before admission, when she developed a chronic cough, productive of small amounts of mucoid sputum, at the same time she began to tire easily and lose weight. Seven months before entry pain in the region of the right neck returned but again passed away within two weeks time. A similar discomfort then appeared in the region of the right axilla, over a palpable, firm, pecan sized mass. This discomfort continued, and the mass gradually enlarged. Two weeks before admission a dull pain (without palpable mass) appeared below the angle of the left jaw. Because of general malaise, weakness, easy fatigability and the gradually enlarging axillary and neck masses, the patient entered the hospital. It was stated that all the masses mentioned had grown slowly and had become firmer, but had remained non-tender and non-inflamed. The overlying skin had remained freely movable, as did the masses beneath it. She denied ever having had tuberculosis, periods of fever, chills, night sweats or hemoptyses.

The physical examination revealed a well developed and well nourished woman in no apparent discomfort. The skin showed a chronic generalized eczema with lichenification in the antecubital spaces, with residual dirty-brown pigmentations over the trunk and limbs, and with patches of depigmentation over the outer aspect of the left thigh, left popliteal space, and the left knee. The right neck bulged and there was fullness over the right shoulder and right anterior upper

chest. This was the result of the presence of various-sized ("olive to egg"), hard discrete, non-tender masses in the region. They were relatively fixed in the neck but movable elsewhere. There were several olive-sized, hard, discrete, movable nodes in the right axilla. The right pectoral and trapezius muscles also contained several more. The trachea was pushed to the left by a mass which filled the suprasternal notch. The inguinal regions were negative. Examination of the heart was negative except for the presence of a soft blowing systolic murmur at the apex. The blood pressure was 120 systolic, 64 diastolic. The lungs showed increased tactile fremitus, vocal fremitus and breath sounds in the entire upper half of the right lung anteriorly and posteriorly. The abdomen was negative. The liver and spleen were not palpated. The pelvic examination was negative.

The temperature was 99.2°F., the pulse 90, and the respirations 22.

Examination of the blood showed a red-cell count of 4,900,000 with 70 per cent hemoglobin (Tallqvist), and a white-cell count of 20,000 with 80 per cent polymorphonuclears, 8 lymphocytes, 9 monocytes, and 3 eosinophils, the smear was normal. The stools were negative. A blood Hinton test was negative. A basal metabolic rate was +17 per cent.

Röntgenograms of the chest showed an ill defined area of consolidation close to the right hilus, and a fusiform area of increased density in the anterior part of the right middle lung field corresponding to the septum between the upper and middle lobes. There was marked soft-tissue swelling of the right supraclavicular area, and some swelling of the right axilla.

The patient remained in the hospital for twenty-three days during which time she ran a Pel-Ebstein type of fever ranging from 99 to 101°F each day. On the fifth hospital day a biopsy of a cervical node was done. The pathological report was lymphoblastoma, Hodgkin's type. X-ray treatment was begun before her discharge, August 21, 1935 (Table 1).

Second Admission (June 9 to 23 1936) The patient had received three courses of x-ray treatment since her discharge from the hospital.

A film taken May 2, 1936 showed appreciable diminution in the area of dullness at the right lung root. She entered for the termination of a pregnancy of about two months duration. Hysterotomy and sterilization were performed four days after entry. All the laboratory findings at this time were negative.

Between the second and final admissions many x-ray films were taken and reported as follows June 29, 1936 the indefinite rounded area of diminished density within the chest was still present and appeared smaller December 10, 1936 the process was slightly less extensive, and the left lung remained clear January 30, 1937 the appearance of the right lung field remained unchanged, on the

diameter was made out at the level of the sixth interspace posteriorly, a large triangular dense shadow filled the right lower medial chest anteriorly June 19, 1938 there was extensive consolidation with fibrosis along the medial aspects of the right lung with displacement of the lung to the right and compensatory emphysema of the remaining lung field on the right, a small focus of con

left side, however, there were two irregular areas of density in the lower lung field, one extending from the level of the fourth rib to the fifth interspace anteriorly, the other lying just above the costophrenic angle February 13, 1937 the area of consolidation on the left had markedly cleared June 19, 1937 there was some increase in dullness laterally from the right hilus shadow October 23, 1937 the process on the right side had not appreciably changed, there was a new ovoid lesion, measuring about 2 by 1.5 cm, close to the left border of the heart September 18, 1937 extensive density still extended out from the right hilar region, the right diaphragm was markedly elevated in its medial portion, the left lung remained clear, there was considerable dorsal scoliosis February 19, 1938 considerable dense, irregularly mottled infiltration was noted radiating from the right hilus involving the medial portions of the right upper and middle lobes, also, what appeared to be a round cavity which measured approximately 1 cm in

solidation was noted at the fifth interspace on the left side laterally August 27, 1938 slight improvement in the appearance of the chest was observed, but the cavities were still present October 29, 1938 there was a destructive process in the right upper lobe with collapse of the right lower lobe, and a localized area of consolidation at the left lower lung field laterally, probably corresponding to the anterior portion of the lower lobe
Final Admission (April 7 to 11, 1939) Since her discharge in June, 1936, the patient had received frequent x-ray treatments which had apparently produced regression in many of the diseased areas previously noted In June, 1937, the patient began to complain of increasing weight loss and hemoptysis There developed a reappearance of matted nodes in the right neck region In August, 1937, or about one and a half years before the final admission, the patient developed discomfort and pain in the right shoulder, with weakness of the right arm, and a classical Horner's syndrome on the right The arm gradually became worse, and

the patient showed much emaciation. After three months of progressively increasing discomfort and pain in the arm, it became completely paralyzed, and a wrist drop developed. The cough became more severe and was productive of considerable amounts of sputum. In spite of continuing weakness, weight loss and easy fatigability she was still able to attend to her housework. Under x ray therapy the use of the right arm began to return. In December, 1938, the paralysis had markedly subsided, the weight had increased slightly, and the general condition improved. However, one month later, in January, 1939, her activities became definitely limited because of shortness of breath, progressively increasing weakness and the appearance of chills, fever, night sweats and upper respiratory infections. The dyspnea became so severe that she noted it on coughing or talking, but there was no chest pain. She was given x ray therapy to the right chest region, as had been done for a number of months previously, but in spite of all efforts, she went progressively downhill and was admitted to the hospital for terminal care.

Physical examination revealed a thin, emaciated cachectic young woman in moderate respiratory distress. There was dullness to flatness, with diminished fremitus and absent breath sounds over the right anterior chest, and coarse, moist inspiratory and expiratory rales with increased breath sounds were heard over the anterior and posterior left chest. Resonance, with bronchial breathing, was heard in an elliptical area overlying the medial border of the right scapula, just inferior to its spine and extending to the eighth rib below. Surrounding this area posteriorly the chest was dull to flat to percussion and the breath sounds were diminished to absent. The heart sounds were almost inaudible due to rales which masked them. The blood pressure was 98 systolic, 68 diastolic. There was a slightly tender, stony hard, nodular, laterally movable mass in the abdomen in the region about the umbilicus. There were many hard, non-tender, bilateral cervical and supraclavicular, pea sized to marble sized masses. Neurological examination revealed that the right pupil (2 mm) was smaller than the left (5 mm). Both pupils reacted to light and accommodation. The external ocular movements were normal and full. The fundi were negative. The right arm was found to lack sensation. Motions of the right shoulder were limited. The right elbow could be flexed only to a right angle. The muscles of the arms were atrophic.

The temperature was 101°F., the pulse 142, and the respirations 25.

Examination of the blood showed a red-cell

count of 5,400,000 with 82 per cent hemoglobin, and a white-cell count of 17,300 with 93 per cent polymorphonuclears, 6 per cent lymphocytes and 1 per cent eosinophils. Stools were guaiac negative. The blood protein was 6.6 gm per 100 cc. Roentgenograms of the chest showed that there was an increase in the destructive process in each side of the lung. The right upper lobe was completely involved, as were the greater portions of the lower and middle lobes. The heart was markedly displaced to the right, due to partial atelectasis. There were several small areas of cavitation visible in the region of the upper and middle lobes. There was an increase in the parenchymatous process of the lung on the left side.

The patient rapidly went downhill and died four days after admission.

DIFFERENTIAL DIAGNOSIS

DR. FREDERICK W. O'BRIEN: I think it is Boyd who quotes Goethe to the effect that what one knows, one sees. Since there was a positive biopsy in this case, I am prejudiced from the start. If you recall, the first film gives the impression of a right upper respiratory infection with some interlobar fluid. The blood picture was as characteristic as is any blood picture of Hodgkin's disease in the early stage. Sometimes you see more of an eosinophilia than is indicated here. We read in the history, "The liver and spleen were not palpated." I do not know precisely what that means.

DR. TRACY B. MALLORY: They were looked for and not found.

DR. O'BRIEN: It is not too unusual for the spleen and liver to appear normal to palpation in Hodgkin's disease. The fever curve referred to on the patient's first admission might make one think of the Pel-Ebstein form of Hodgkin's disease but could go equally well with tuberculosis. Tuberculosis and Hodgkin's disease in the same patient occur in young persons but are rather rare in adults. There is nothing said here about the character of the nodes. I presume because they were non-tender and non-inflammatory that they were not tuberculous nodes. Were any sputum examinations done in this case, and, if so, were bacilli found?

DR. MALLORY: They were never demonstrated, I can assure you. I think we can be sure they were looked for.

DR. O'BRIEN: Following x ray treatment there was an apparent change in the size of the area of infiltration seen close to the right hilus in succeeding films, however, I think it is more apparent

than real as one compares the series. If we look closely the suspicion of abscess formation arises. Following x-ray therapy one might expect some clearing of such a lesion. I am inclined to rule out tuberculosis because the lesions in the films which show a definite contralateral spread cleared up almost overnight after x-ray treatment. Furthermore, there was a Horner's syndrome in this case. I am not familiar with its occurrence in pulmonary tuberculosis. Brucellosis comes to mind in the differential diagnosis. Parsons and Poston* at Duke University recently reported 4 cases of brucellosis where the histopathology of the nodes was believed identical with that of Hodgkin's disease. Brucellosis, however, does not show the progressive lung changes seen here and I believe only affects the lungs terminally. Among the unusual things one must consider actinomycosis. It too may be a long-standing process but, as I understand it, does not involve the nodes, may involve the chest wall and is always accompanied by a sinus. In the presence of supraclavicular nodes, Horner's syndrome and the roentgen picture, carcinoma is a possibility. There is no evidence of rib destruction, which is seen in primary-sulcus tumor. Oat-cell cancer of the lung may improve under irradiation, but in any type of lung cancer I should not expect a generalized adenopathy of axillas, groins and mediastinum such as we have in this case, so that I am forced back to a diagnosis of Hodgkin's disease with infection. I say with infection because in the later films you see what appears to be cavity formation in an otherwise dense right upper lobe, and so far as I can learn, cavity formation does not occur in Hodgkin's disease except in the presence of superimposed infection. Interstitial involvement of the lungs occurs in about 30 per cent of the cases of Hodgkin's disease. One thing I should like to ask—I see no mention of it—is whether or not the nodes regressed under x-ray treatment.

DR EDWARD A GALL: They did originally. Later on the mass in the neck subsided only slightly.

DR O'BRIEN: One might well wonder whether the changes seen on the film in the right upper-lung field were brought about by overenthusiastic radiation. When you have a patient as ill as this one was and as badly in need of attention, it is difficult to treat the patient otherwise, but I think sometimes that we overirradiate. The question arises here whether irradiation produced the changes we see. They are not characteristic of any pulmonary fibrosis that I have recognized

as such following radiation. So I am forced again to conclude that we are dealing with Hodgkin's disease with superimposed infection.

DR MALLORY: Some of the audience may be interested in hearing more about this last question that Dr O'Brien has raised. What dosage of x-rays is necessary to produce x-ray pneumonitis?

DR O'BRIEN: I do not believe anyone knows. The individual case differs. We have had patients who received more irradiation than this woman with only a resultant fine pulmonary fibrosis, certainly nothing similar to what we see here. I do not believe this was all due to radiation.

DR JOHN H TALBOTT: I should like to raise the question of whether or not this may be acanthosis nigricans with peripheral manifestations. The skin pigmentation suggests that diagnosis so far as the first physical examination was concerned.

DR GALL: She had had that all her life.

DR LINGLEY: I should like to ask Dr O'Brien if he thinks it is necessary to postulate infection because of the presence of cavities in the lungs.

DR O'BRIEN: I have no authority for it, outside of talking to Dr Frederic Parker, Jr. His belief is that you do not see cavitation in Hodgkin's disease without superimposed infection.

DR DONALD S KING: We have seen cavities disappear under x-ray treatment.

DR LINGLEY: Yes. I remember 2 cases of Hodgkin's disease which were treated by x-ray with disappearance of the cavities, but we were never able to find infection. One of these cases came to postmortem and was still straight Hodgkin's disease.

DR KING: Of course you did not prove that it was not infected at the time.

DR LINGLEY: There is no characteristic fluid level which we should expect, and no pus or temperature or anything else to go with it.

PATHOLOGICAL DISCUSSION

DR MALLORY This is a case where the pathologist, too, does not escape without a good many perplexities and troubles. When this patient came to autopsy the lungs presented a very extraordinary picture, unlike anything we had ever seen before. All five lobes showed lesions of one sort or another, and they differed in all five lobes. It is almost an impossible job to untangle the entire story. She had, of course, Hodgkin's disease. That had been proved at the original biopsy, and she still showed active characteristic Hodgkin's involvement of many lymph nodes at the time of autopsy. Even at the time of death the liver and spleen were free. The lungs contained a great many nodules that were clearly due to Hodgkin's disease. In addition, however, there were some other things. For instance, there was an ordinary terminal bronchopneumonia, undoubtedly infectious in origin, not extensive, but enough to complicate the picture. There were still some cavities at the time of autopsy. These cavities showed nothing to suggest tuberculosis. I should also be inclined to say that they showed nothing to suggest infection, although I think that is difficult to rule out. One of the most striking features was the right upper lobe which was completely lacking in air and was of a uniform leathery consistence. I think the degree of dense fibrous consolidation in the upper lobe is not indicated adequately in any of the films. It had shrunk enough so that the apparent apex of the lung consisted actually of the apex of the lower lobe. Aerated lower lobe tissue lay behind the upper lobe at all points, so that in the x-rays we get the appearance of at least some air in the apex of the lung, whereas there actually was none in the upper lobe.

Microscopic examination showed solid fibrosis of this entire lobe with extremely dense collagen and just an occasional remnant of an alveolus lined with cuboidal epithelium. Throughout this fibrous mass, however, one could still recognize persistence of alveolar walls. The elastic tissue had not been destroyed, and there was an alveolar pattern that could be brought out with the elastic tissue stain but which was quite invisible with the hematoxylin and eosin stain. Where we found recognizable Hodgkin's involvement of the lung in this case, there was always complete destruction of the lung architecture. In the upper lobe there was fibrous obliteration of all the air sacs but the architecture was not obliterated. Either this was once Hodgkin's disease and all the Hodg-

kin's cells were killed or sterilized by x-ray so we could no longer recognize them, or we must assume that this fibrosis of the entire lobe was due to something else. I can only guess what that something else might be. The largest mass of nodes was in the lower right neck and was very resistant to therapy. She had a great many treatments to the right side of the neck, and many treatments to the mediastinum and chest. Therefore there was a possibility of a good deal of cross-firing, and much of the radiation that she had may have accumulated in this one area. The experimental production of x-ray pneumonitis has never been carried to such an extent as to produce anything like this picture. I cannot say that it has ever been proved that radiation pneumonitis can consolidate a lung to this extent, but I think it is more likely that the changes were produced in that way than that they were a part of the Hodgkin's involvement.

DR MAURICE FREMONT SMITH What would be the effect of long standing atelectasis? Do you get a picture comparable to that?

DR MALLORY I have never seen such a picture from pure atelectasis alone. The architecture is still further complicated by the fact that there is very extensive obliteration of the blood vessels throughout the area. This is unusual in organized pneumonias. There is fibrous plugging of bronchi as well as alveoli. There is in some places in the lung, but not in this right upper lobe,—which is most puzzling,—actual tumor thrombosis of blood vessels by the Hodgkin's disease thus accounting for small areas of infarction. However, infarction always destroys the lung pattern so that we can exclude it so far as the upper lobe is concerned. The walls of the various cavities again showed fibrosis and no recognizable Hodgkin's disease.

A PHYSICIAN Did the Hodgkin's disease invade the bronchi?

DR MALLORY It had grown around the bronchi in many places, but so far as we could make out had not invaded them, certainly not the larger ones.

DR ALFRED KRANES Is it not unusual to have radiation fibrosis confined to one lobe?

DR MALLORY There are many spots of a similar process scattered throughout the other lobes. These can apparently be distinguished from the Hodgkin's disease. All the other foci are relatively small compared with this one major involvement in the right upper lobe.

CASE 26242

PRESENTATION OF CASE

A sixty-four-year-old man was admitted to the hospital because of mental disorientation with chills and fever.

Without apparent cause, approximately seven days before admission, the patient developed chills and a fever of 103°F, followed by a profuse sweat. A physician was called who prescribed "pills" and ordered the patient to remain in bed. However, his temperature remained at 100.6°F and he continued to have "chilly sensations." Five days before admission he arose from bed still feeling chilly, but otherwise fairly well. The following day he went to work as usual, but that evening he "shook all over." On the third and second days before entry he remained at home, but out of bed, saying that he felt fairly well, but on the evening of the second day before entry, he again felt very chilly and afterward became warm. He became overtalkative and seemed unreasonable and somewhat confused. His physician was called, and the temperature was reported as having been 105°F. The confusion persisted and increased somewhat on the day before admission and the temperature remained at 103°F all day. A pill prescribed by his doctor was vomited. Communication with the patient became somewhat difficult because of his confusion. Nevertheless his relatives believed that he had experienced headaches for some twenty-four hours before admission. Because of his symptoms he was admitted for study.

The past, marital and family histories were non-contributory.

Physical examination revealed a comatose, well-nourished man with shallow, slow, stertorous respirations. The skin was warm, clear and dry. The tongue was held in the mouth and appeared rough, moist and moderately coated. The throat was injected but without an exudate. Examination of the lungs was unsatisfactory because of shallow respirations. There was dullness at the bases posteriorly, up to the level of the ninth or tenth thoracic rib on each side. There were no definite signs of consolidation. The heart was described as normal. Examination of the abdomen was negative. There were varicose veins in the lower legs. Before admission the patient had been given morphine, and it was thought that part of the narcosis on entry was due to this.

The temperature was 103°F, the pulse 75, and the respirations 24.

A neurological examination, performed on the

third hospital day, revealed the following findings. The patient was in semistupor, from which he could be aroused without difficulty. He replied to questions with single words and at times apparently had considerable difficulty in finding a word. He named most familiar objects correctly, but failed with a pencil. Co-operation was not very good. The fundi were not definitely abnormal. The temporal margins of the nerve heads were sharp, and the nasal margins only slightly hazy. The visual fields were full. The pupils were normal. The external ocular movements were normal, and there was no nystagmus. There was a questionable right facial weakness when pressure was applied to the eyeballs. The right handgrip was weaker than the left. The tendon reflexes were a shade more active on the right. The abdominal reflexes on the right were absent, on the left, positive. The neck was rigid. The plantar responses were normal. There was no tenderness over the sinuses or mastoids.

Examination of the blood showed a red-cell count of 3,400,000 with 111 gm hemoglobin (photoelectric-cell technic), and a white-cell count of 35,000 with 94 per cent polymorphonuclears. The platelets were increased. Examination of the urine showed + to +++ albumin. The sediment on a few occasions showed from 1 to 5 red blood cells per high-power field. These occasional findings of hematuria were noted throughout his hospital stay. The blood Hinton test was negative. The serum nonprotein nitrogen varied from 25 to 43 mg per 100 cc, but was usually normal. A lumbar puncture revealed a spinal fluid which showed an initial pressure of 400 mm of water with a white-cell count of 3600 with 75 per cent polymorphonuclears, a total protein of 315 mg per 100 cc, a sugar test of 19 mg per 100 cc, chlorides of 639 mg per 100 cc and a gold-sol test of 4455556541. Culture and smear of the spinal fluid were negative for pathogenic bacteria.

Roentgenograms of the chest and mastoid regions were negative. The left antrum and frontal sinuses were slightly diminished in radiance. The superior wall of the left frontal sinus was hazy in outline and there was definite mottling in the frontal bone just above it. The appearance was suggestive of osteomyelitis, but further films did not confirm this finding.

A Type 29 pneumococcus was cultured from the sputum and blood. He was given sulfapyridine by mouth until the blood level reached as high as 161 mg per 100 cc, but the levels averaged around 6 to 10 mg. He responded poorly to this therapy, however, so it was augmented with Type

29 antipneumococcus rabbit serum, in amounts equaling some 140,000 units. In spite of this and frequent transfusions, fluid parenterally and orally, adequate sedation and general nursing care, the disease continued to run a stormy course. The physical and neurological examinations remained essentially the same throughout his hospital stay, except that at one time a faint systolic murmur was heard over the precordium, but this had occurred at a time when there was a high fever. Microscopic hematuria persisted, and the urinary sediment contained pyridine crystals. No stabs of pain were complained of, and no petechiae or clubbing of the fingers was noted. The clinical picture, rather, was focused entirely on the central nervous system where there were never any localizing neurological signs.

The patient remained in the hospital for twenty nine days, during which time his temperature spiked from 98 to 106°F and the pulse and respirations were likewise irregular. The antibody content of the blood against Type 29 pneumococcus was found to be high. Type 29 pneumococci were agglutinated by serum in dilutions up to 1:64. Because of the failure of all therapy, artificial fever treatment was attempted for a period of a few hours, but to no avail. Repeat lumbar punctures showed essentially normal pressures with high cell counts, proteins ranging around 240 mg per 100 cc., sugars around 20 mg per 100 cc., and chlorides about 595 mg per 100 cc. The spinal fluid contained neither agglutinins nor precipitins against Type 29 pneumococci. Accordingly the Swift-Ellis type of treatment was attempted, with the introduction of a few centimeters of the patient's serum into the spinal canal, but this proved of no avail. During the last ten days of the patient's life he ran a spiking temperature, ranging daily from 99 to 104°F, with corresponding swings in pulse and respirations from 100 to 130 and 30 to 35 respectively. The patient gradually grew weaker and less responsive and then suddenly, without warning, died on the twenty ninth hospital day or the thirty sixth day of his illness.

DIFFERENTIAL DIAGNOSIS

Dr. AUGUSTUS S. ROSE. The laboratory studies in this case delimit our problem. It is clearly indicated that we are dealing with a severe infectious process due to Type 29 pneumococcus. The clinical features suggest a meningitis, but as I will point out there are indications that the meningitis was secondary rather than primary and was not the actual cause of death.

If I might briefly review the important features

of the history, the patient was a sixty four year old man who suddenly without warning or apparent cause began to have chills and fever but who for five days was otherwise reasonably well. In fact on the fifth day he went to his work. The day before that he was up all day. Then suddenly, two days prior to admission, he became confused and overtalkative, and then gradually became semicomatose. When he entered the hospital we find that he had fever, a relatively slow pulse, stertorous respirations and stiff neck—signs which strongly suggest increased intracranial pressure and meningeal infection. This was later confirmed by lumbar puncture. The neurological examination indicated the possibility of changes in the left cerebral cortex or hemisphere. There was a questionable right facial weakness. The reflexes were slightly more active on the right side than they were on the left. The abdominal reflexes were absent on the right and he had some difficulty in choosing words. Any one of these findings alone would be difficult to interpret, but the fact that they all occurred together points definitely to some sort of localized abnormality in the left hemisphere. With the finding of cells in the spinal fluid and a sugar of 19 mg per 100 cc. we are in a position to say that the patient had a bacterial meningitis, in spite of the negative culture from the spinal fluid. The question arises, Where did this meningitis come from? I think we are safe in assuming that it was due to the pneumococcus. Pneumococci usually enter the meninges from two sources by direct extension from the paranasal sinuses or mastoid, or by way of the blood stream. The history in this case points to the blood stream as the probable source, but x-ray films suggested osteomyelitis of the left frontal sinus. Pneumococcal meningitis is a severe and often an overwhelming infection, and I do not believe that the first four days of this man's illness are consistent with that diagnosis. It is more likely that the meningitis developed two days before admission when his condition suddenly changed.

May we see the x-ray films?

Dr. RICHARD SCHATZKI. The x-ray evidence boils down to the appearance of the frontal sinuses. The other sinuses are fairly clear though there may be some chronic disease in one antrum. The left frontal sinus is different from the right. The wall is preserved but is less distinct than the one on the right side. These films were taken six days apart. The adjacent portion of the left frontal bone shows localized decalcification. How long had he been ill?

DR ROSE His symptoms began approximately one week prior to the time when the first x-ray film was taken

DR SCHATZKI These questionable areas are sharply defined, more so than one would expect from osteomyelitis of one week's duration. I think one can exclude osteomyelitis of six days' duration. I do not see any definite pus in the sinus. I think it could be an osteomyelitis of, let us say, three weeks' duration.

DR ROSE The report indicates that the second films did not confirm the findings of the first.

DR SCHATZKI I think the examiner changed his mind, because the films are practically the same.

DR F DENNETTE ADAMS Was there a chest plate?

DR SCHATZKI It does not show anything abnormal.

DR ROSE We are left somewhat in the air, having x-ray evidence that he possibly had a frontal sinusitis that might be of longer duration than his present illness although the early part of his illness hardly suggests this diagnosis. Certainly our record gives no history which leads us to suspect an acute frontal sinusitis. There were present none of the signs of a sinusitis or an osteomyelitis such as are usually found when extension of infection to the meninges occurs, for example, swelling or tenderness. So, I take the point of view that, if he had a sinusitis, it was probably of no significance in the development of his meningitis, unless it served as a possible source of the blood-stream infection. We are left, therefore, with the blood stream as the probable origin of his meningitis. The entire illness will be explained, it seems to me, if we can interpret the first five days of his illness. The history of chills and fever is consistent with a septicemia or at least a bacteremia, which we know was present shortly after admission.

We must now consider the possible sources of the pneumococcal bacteremia. We first turn to the respiratory tract and again find no evidence in the history. He had had no respiratory infection, complained of no sore throat or pain in the chest. The x-ray films of the lungs were negative, and although the throat was injected, apparently this was not due to a real pharyngitis. Nevertheless, the sputum contained pneumococci. We have mention of the veins of the leg as a possible focus, but we are told that there was no evidence of infection in them. We must, therefore, consider the heart as the possible source. Indeed, the entire

illness can best be explained by the diagnosis of pneumococcal endocarditis, even though it began without evidence of an infectious focus. For five days he had repeated episodes of chills and fever. He then suddenly became confused and semicomatose and showed signs of meningitis and of a questionable localized lesion in the left cerebral hemisphere. The illness was terminated after a protracted but steady downhill course with a picket-fence temperature curve and in spite of adequate treatment. The laboratory findings showed an anemia of moderate grade and red blood cells in the urine on a number of occasions. The physical examination, however, does not offer much support. There were no petechiae. The spleen was not enlarged, and the finding of a systolic murmur on one occasion was modified by the statement that it was heard at a time when the temperature was elevated. Nevertheless, in the absence of any other demonstrable focus, the clinical course of the disease is strongly in favor of this diagnosis.

Before considering this as the only diagnosis, we ought to consider the possibility of a brain abscess which existed prior to the development of his symptoms, with rupture of the abscess producing the sudden onset of meningitis and subsequent infection of the blood stream and a continuous downhill course. I believe that the evidence is against a brain abscess that developed either before the onset of his present illness or during it. The fundi were normal, indicating that he did not have chronic increased pressure, although the first lumbar puncture showed an elevation of pressure. Furthermore, repeated tapings showed that the pressure subsequently remained low. This would not be expected if an abscess was present. In addition, the neurologic signs did not change significantly, as would be the case in an expanding lesion.

I am not sufficiently informed to discuss the therapy administered in this case except to say that a sulfapyridine level in the blood of 6 to 10 mm is a level which is capable of producing a satisfactory therapeutic response. I do not know why fever therapy was used and I am puzzled by the use of the term "Swift-Ellis treatment," by which is usually meant the injection of neoarsphenamin intravenously and the subsequent injection of the patient's arsphenaminized serum intrathecally. Did they use neoarsphenamin?

DR TRACY B MALLORY I do not believe any neoarsphenamin was given. They merely injected his own serum into the spinal canal, in order to produce a higher concentration of antibodies in the subarachnoid space.

DR. ROSE In summary, therefore, I believe the evidence points to the diagnosis of pneumococcal bacteremia with secondary pneumococcal meningitis and possibly septic cerebral infarct and pneumococcal endocarditis.

DR. CHARLES L. SHORT I saw this case for only one purpose and that was to give fever therapy. The reason for this rested on some experiments showing that pneumococci *in vitro* may be more susceptible to sulfapyridine if the temperature is raised. So, all other measures having apparently failed, this patient was given fever therapy with radiant heat and his temperature kept above 103°F for about four hours. This principle of treatment is not new. It has been used in the treatment of syphilis, combining chemotherapy with fever therapy, and also in the treatment of gonorrhea. As you see, there was apparently no beneficial effect from the fever therapy.

To answer Dr. Rose's comment, the patient it is true, was having fever all along but if you examine the chart you can see that he was running a low fever with occasional spikes, but only after the fever therapy did he go into the period of intermittent high pyrexia.

DR. CHAMBERLYN We did a great deal of laboratory work which in retrospect is interesting. In the first place, he had a negative spinal-fluid culture on entry with a positive blood culture. That should have been of a great deal of significance in the light of the subsequent diagnosis of endocarditis, because a true spreading leptomeningitis should give positive cultures in the spinal fluid. On entry he had no agglutinins in the blood or spinal fluid. With full blown endocarditis we are accustomed to find a maximal concentration of agglutinins in the blood serum. Dr. Kubik and I talked over the question of endocarditis at that time, but there was no supporting clinical evidence. I believed that endocarditis could be fairly well excluded and Dr. Kubik also thought that it was unlikely. After we gave him immune serum the serum agglutinin level came up to 1:12, but instead of dropping it progressively rose during the subsequent hospitalization to a concentration of 1:64. That is an extremely high agglutinin titer and one which I believe should be diagnostic of endocarditis. He had negative chest signs, and we were never able to demonstrate any pulmonary infarction which one might have expected to find had the intravascular sepsis been a thrombophlebitis rather than an endocarditis. The subsequent blood cultures were negative by the routine method and in dilutions, but there was one experiment which was rather interesting. The question of sulfapyridine fastness of this organism came up. We took his

blood containing pyridine in a known level and a normal blood with a similar amount of pyridine and did a bactericidal experiment. The normal blood killed the pneumococcus perfectly well although there were no agglutinins in the serum, whereas the patient's blood contained agglutinins but failed to kill the organism. We have as yet no explanation for that. It may be that the blood contained some pneumococci which we were unable to grow because of the concentration of the pyridine. But when we intensified the bacterial implantation by adding bacteria to the blood we increased the size of the inoculum sufficiently to overcome the bacteriostatic effect of the pyridine.

I should like to point out the fact that this method of using immune serum intrathecally is hazardous. We believe it is in general a bad principle in the treatment of meningitis. Sufficient meningeal irritation may occur to permit further abscess formation, hence there may not be so many successful recoveries if serum is used intrathecally. I believe from these studies that we have followed this patient from the onset of an endocarditis through to its fatal termination.

DR. CHARLES S. KUBIK It might be of interest that there were 175 red cells in the first spinal fluid, 75 in the second two days later and again in the third fluid five days after that, but none subsequently. In the other cases of meningitis complicating bacterial endocarditis there have usually been some red cells, often a larger number than in this case. The combination of red cells in a purulent fluid, and particularly a xanthochromic purulent fluid, while not diagnostic, should lead one to think of subacute bacterial endocarditis. As Dr. Lyons has remarked we considered that as a possibility when the patient was first admitted but did not give it enough consideration later.

CLINICAL DIAGNOSES

Bacteremia (Type 29 pneumococcus)
Pneumococcal meningitis.
Multiple meningeal abscesses?

DR. ROSE'S DIAGNOSES

Pneumococcal bacteremia.
Pneumococcal meningitis (secondary)
Septic cerebral infarction?
Pneumococcal endocarditis?
Chronic frontal sinusitis?

ANATOMICAL DIAGNOSES

Bacterial endocarditis, acute, Type 29 pneumococcus.
Pneumococcal meningitis, embolic.

Infarcts of spleen and kidneys
Exostosis of orbital plate of frontal bone

PATHOLOGICAL DISCUSSION

DR MALLORY The autopsy did show bacterial endocarditis. There were very large vegetations—1 to 2 cm in diameter—on the mitral valve. There was no evidence of any preceding rheumatic involvement of the valve, but we know that with pneumococcal endocarditis such precedent valvular deformity is not necessary. There were

emboli and consequent infarction in the spleen and kidneys. In the brain there were no gross infarcts, but there was a fairly diffuse meningitis. Microscopically small areas of partial infarction were noted. The frontal sinuses showed no infection, but there was a unilateral hyperostosis behind the left one which undoubtedly accounts for the unusual x-ray picture.

DR ADAMS How often do you see pneumococcal endocarditis arise out of a clear sky?

DR MALLORY It is not very common but it does happen.

PROLONGED RESIDENCIES THEIR EFFECT ON MEDICAL EDUCATION

DURING the last twenty years there has been an evident tendency toward the prolongation of the periods of medical internship and residency. With the development of the boards of certification in the specialties this has been accelerated, and now that internal medicine and general surgery are included, it has become a problem of major importance to the entire profession. Schedules of four, five and even six years have been recommended or put into effect. As yet, however, little consideration has been given to the ways in which such a radical shift will affect medical education, hospitals and the young physicians who must go through this prolonged and rigorous training, and finally the practice of medicine. The following paragraphs deal with the first of these problems, and the others

will be discussed in subsequent issues of the *Journal*.

There are two phases of medical education, each characterized by emphasis on a particular educational method. One, which may be termed the academic, is devoted to the accumulation of knowledge of the fundamental sciences on which medicine is founded—the biology of man, the second consists of training in the application of these sciences to clinical practice and of familiarization with the techniques involved. The former is appropriately provided by an academic institution, the latter can best be acquired by an apprentice system that involves gradually increasing responsibility under adequate supervision—in present-day terms, an internship or residency. On the appropriate application of these two educational methods and on a proper balance between them depends the success of medical education.

In this country the emphasis has swung pendulum like from one to the other. The apprenticeships of the Colonial Era and the early years of the Republic gave way, with the founding of medical schools, to a period of unalleviated didacticism in the middle portion of the last century. The reintroduction of bedside teaching in the rapidly growing charity hospitals started a trend in the reverse direction, which developed steadily into the clinical clerkships and intern systems of the first third of this century. To-day, with internship and residency programs stretching over periods of four to six years, apprenticeship dominates medical education to an even higher degree. But since it is in hospitals that this apprenticeship must be served now and in the future, one may reasonably ask, How many hospitals possess staffs capable of offering a genuinely educational program over so extensive a period? Dean Rappleye,* of Columbia, after prolonged study of the situation, is justifiably skeptical of their ability and, almost alone among the administrators of the large medical schools, calls for close co-operation between schools and hospitals in the development of such programs.

The great majority of medical schools have stood decorously aloof or have more or less openly im-

*Rappleye, W. C.: The challenge to medical education. *J. A. M. A.* 1941, 114, 1940.

plied that this phase of medical education is no concern of theirs. Yet it is from those who are trained by this apprenticeship that their clinical faculties will soon be recruited. Far from evincing concern over the diminishing proportion of medical education that they control they have treated with almost complacent neglect the recommendation of the Advisory Board of Medical Specialties, namely, that all candidates return after a period of internship to a further year of work at the medical schools in one or more of the basic sciences.

Is the preclinical training in the present medical schools so adequate that such a year would be superfluous? Does anything more fundamental than custom and administrative convenience demand that all academic work should precede the first contact with a sick human being? Experience in teaching a basic science not only in the preclinical period but also to fourth-year men and graduate students strongly indicates that the answer to both questions should be, No. Furthermore, in many other fields of education, experiments in the alternation of periods of academic instruction with those of practical experience have proved highly successful, and the avidity with which graduate students seize on scientific material which can be correlated with clinical experience indicates that the method is pedagogically sound.

Surely the time is ripe for a re-evaluation of all medical education. In view of the appalling number of years to which it has been prolonged this can hardly be too extensive. The study should include the premedical years, with a view to the admission of students to the medical schools at an earlier age. It should consider the feasibility of telescoping at least one of the clinical years into the basic internship, and it should seriously consider the advisability of a return to academic work after internship for those desiring advanced training.

MILK GOOD, BETTER, BEST

CONSIDERABLE water has gone over the dam in the last two or three years in relation to the milk industry, none of it has gone into the milk, either

chemically or economically. Milk standards have tended steadily to improve, milk profits have continued to be precarious, with relatively high costs of production and an uncertain and unsatisfactory volume of consumption. Government, union and farmer-labor price-fixing, Mayor LaGuardia's public proclamation urging substitution of Grade B for Grade A milk to combat the cost of the latter, and the blast at the business in the November issue of *Fortune*, under the title "Let 'Em Drink Grade A," have not served to smooth the path of an essential industry.

The main theses of the broadside in *Fortune* were that consumers do not use so much milk as they should because of high price, that the price of milk is too high and could be reduced, that milk can be sold through stores at four cents a quart less than through home-delivery, that organized labor and organized farmers have in many markets arbitrarily raised wages and farm prices to uneconomic levels, and that the milk distributor has helped to support this policy in order to keep consumer prices at high levels. Dr. Edward Fisher Brown, writing for the Milk Research Council, refutes these statements. Price of milk is not arbitrarily set by money-grabbing milk companies, but is determined by a number of relatively fixed charges—a price paid to the farmer that is set in many important markets by the federal or state government, a wage scale negotiated with labor unions, the cost of supplies and taxes. Retail price is raised but little by company profits, this increase was shown by an audit in New York State not to exceed three-eighths of a cent a quart. Furthermore, Dr. Brown points out that high consumer prices diminish consumption, and that profit comes not with decreased but with increased consumption, hence the main interest of dealers is to cut costs, thus increasing the sale of milk.

The policy of milk grading is a sound one, excluding the ballyhoo that has been raised about certain fancy "premium" milks. From a medical point of view there should be some guarantee that all grades of milk are safe. This is ensured if minimum standards are invoked as in Boston, where market milk may have no more than 400,000

bacteria raw, and, of recent date no more than 20,000 pasteurized, and can be sold only pasteurized. Grade A milk may now have only 50,000 bacteria raw, and 5000 pasteurized, and certified milk, produced under the direction of the Boston Medical Milk Commission, may have only 5000 bacteria in its raw state and only 100 after pasteurization. Add a price difference of only four or five cents a quart between certified and Grade A milk, and the choice of the former as the milk par excellence seems justified.

Even assuming that all grades of milk are safe for the consumer, the marketing of better grades of milk with fewer bacteria, more calories, greater freshness and a higher vitamin and mineral content is logical, sound and ethical business. No reason exists for abolishing porterhouse steak simply because some consumers can afford only hamburger. In this direction lies totalitarianism.

MEDICAL EPONYM

CARDARELLI - OLIVER SIGN

"Sulla pulsazione del tubo laringotracheale, come segno di certi aneurismi dell'arco aortico [Pulsation of the laryngotracheal tube as a sign of certain aneurysms of the aortic arch] was described by Professor Antonio Cardarelli (1831-1927) in *Il movimento medico-chirurgico* (1 223-229, 1872). A portion of the translation follows:

On observing the anterior aspect of the neck, I noted that the whole laryngotracheal tube was shaken by a rhythmic and easily perceptible impulse, and this was all the more noteworthy and important since the pulsation of both carotid arteries was feeble. This pulsation of the laryngotracheal tube was much more notable in another case [in which] it was not only perceptible on laying the fingers on either side of the tube, but was perceptible on inspection of the thyroid gland, which with every arterial pulsation was carried toward the right.

Six years later, the following letter from Surgeon Major W S Oliver, dated September 13, 1878, was printed in the *Lancet* (2 406, 1878), under the title "Physical Diagnosis of Thoracic Aneurism."

As the diagnosis of thoracic aneurism of the aorta is often difficult and obscure, notwithstanding the various physical means we have now at our disposal for detecting it, I am desirous of mentioning a method of examination which has afforded me material assistance in diagnosing this disease (or even simple dilatation of the vessel) when it occurs as is most generally the case, either in the ascending or the first part of the transverse portion of the arch.

The process is as follows: place the patient in the erect position, and direct him to close his mouth and elevate his chin to the fullest extent, then grasp the cricoid cartilage between the finger and thumb and use gentle upward pressure on it, when it dilatation or aneurism exists, the pulsation of the aorta will be distinctly felt transmitted through the trachea to the hand. The act of examination will increase laryngeal distress should this accompany the disease.

PYELITIS OF PREGNANCY TREATED WITH SULFANILAMIDE

Mrs. D J C., a twenty-eight year-old primipara thirty-six weeks pregnant, was seen at home on March 20, 1939, because of severe back pain, chilliness and general malaise. On examination the temperature was found to be 100.6°F., and the pulse 115. There was marked bilateral costovertebral tenderness. A probable diagnosis of acute pyelitis was made, and the patient was sent to the hospital.

The patient's past history was essentially negative. Catamenia began at fourteen, were regular with a twenty-eight-day cycle and lasted four days without pain. The last period was July 16, 1938, making confinement due April 23.

The patient was first seen on September 18, 1938, at which time a physical examination was essentially negative except for an enlarged uterus which was consistent with the duration of the amenorrhea. The urine was negative. The hemoglobin was 70 per cent, and because of this, the patient was told to take 5 gr of ferrous sulfate three times a day.

Except for some gastric disturbance, possibly due to the iron, the pregnancy progressed uneventfully until the date above mentioned. On admission to the hospital the white-cell count was found to be 15,000 and a catheter specimen of urine showed a large amount of pus. The hemoglobin was 52 per cent, and the red-cell count 3,030,000. She was started at once on 15 gr of sulfanilamide four times a day and a red-cell count and hemoglobin determination were made every other day.

On March 21 the temperature did not go above

A series of selected case histories by members of the section will be published weekly, questions and questions by subscribers are solicited and will be discussed by members of the section.

99.2°F, and thereafter was normal. She was discharged on March 25, completely relieved symptomatically but still showing pus cells in the urine. Urine culture had shown a colon-bacillus infection. Sulfanilamide was discontinued when she was discharged from the hospital.

The patient continued to show pus in the urine but remained symptomatically well and afebrile until April 15, when she had a recurrence of back pain with a temperature of 102°F and was readmitted to the hospital. She was again started on 15 gr of sulfanilamide four times a day. On April 16 the temperature was 101.2°F, on April 17 it was normal. Vaginal examination showed the head engaged in the pelvis, the cervix partly taken up and the os almost admitting two fingers. In view of the proximity to term and the state of the cervix, it was decided that induction of labor was the best treatment. This was done, and the patient was delivered of a 7-pound, 5-ounce, infant in good condition. In view of the urinary infection, it was thought best to forestall any urinary retention by immediately putting the patient on constant drainage. Sulfanilamide was omitted following delivery. The puerperium was entirely afebrile. The catheter was removed on the fourth day, following which the patient voided normally. The patient was discharged well on the fourteenth day. Examination of the urine a week later showed no pus.

Comment. Sulfanilamide in the treatment of pyelitis during pregnancy has had such success that it is probable that its use will become routine. The results in this case in which no renal lavage was undertaken would lead to the belief that lavage of the kidney is perhaps entirely unnecessary. It is much too soon to draw any conclusions as to whether the drug prevents the kidney damage that was seen so often following recurrent attacks of pyelitis.

VETERANS' INFORMATION ON DEATH CERTIFICATES

The attention of all fellows is invited to Sections 9 and 10 of Chapter 46 of the General Laws which require that the status of the deceased as a veteran must be determined by the physician signing the death certificate. Failure to supply this information renders the physician liable to a fine.

There has been some misunderstanding on the part of local authorities in this connection, and in many cases the entire death certificate, with the exception of the medical certificate, is filled out by the undertaker or other persons.

It is understood that the Secretary of State is preparing a new form to correct this misunderstanding but, in the

meantime, great care should be used by the physician in checking this item.

ALEXANDER S. BEGG, M.D., *Secretary*

DEATH

STANLEY—JOSIAH M. STANLEY, M.D., of Northboro, died June 4. He was in his eighty-first year.

Born in Methuen, he attended Yale University and received his degree from the New York University Medical College in 1884. After serving his internship at Bellevue Hospital, New York City, he took a postgraduate course at Harvard Medical School.

Dr. Stanley was town and school physician for twenty-five years in Northboro. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

Erratum. Through an error, it was announced in the June 6 issue of the *Journal* that Dr. George G. Sears died on May 27, the correct date is May 28.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR APRIL, 1940

| DISEASES | APRIL 1940 | APRIL 1939 | FIVE YEAR AVERAGE* |
|--------------------------|---------------|---------------|-----------------------|
| Anterior poliomyelitis | 0 | 1 | 0 |
| Chicken pox | 1286 | 719 | 1058 |
| Diphtheria | 11 | 9 | 17 |
| Dog bite | 937 | 938 | 916 |
| Dysentery bacillary | 24 | 7 | 5 |
| German measles | 55 | 96 | 1939 |
| Gonorrhea | 368 | 355 | 440 |
| Lobar pneumonia | 522 | 607 | 577 |
| Measles | 2464 | 4063 | 3242 |
| Meningococcus meningitis | 5 | 4 | 16 |
| Mumps | 756 | 708 | 1052 |
| Paratyphoid B fever | 3 | 0 | 8 |

| Whooping cough | 625 | 798 | 105 |

*Based on figures for preceding five years.

RARE DISEASES

Diphtheria was reported from Fall River, 3, Fitchburg, 1, Lawrence, 1, Northbridge, 1, Somerville, 1, Watertown, 1, Wrentham, 3, total, 11.

Dysentery, bacillary, was reported from Arlington, 3, Belchertown, 7, Belmont, 1, Boston, 1, Brookline, 2, Greenfield, 1, Lowell, 8, West Boylston, 1, total, 24.

Malaria was reported from Cambridge, 3, total, 3.

Meningococcus meningitis was reported from Brockton, 2, Framingham, 1, Orange, 1, Quincy, 1, total, 5.

Paratyphoid B fever was reported from Beverly, 1, Dedham, 1, Milton, 1, total, 3.

Pellagra was reported from Boston, 1, Winchester, 1, total, 2.

Pfeiffer bacillus meningitis was reported from Charlestown, 1, total, 1.

Septic sore throat was reported from Belmont, 1, Beverly, 1, Boston, 4, Brockton, 1, Cambridge, 4, Chicopee, 1, Fall River, 1, Georgetown, 1, Lexington, 1, Lynn, 1,

Malden, 3 Medford 4 Melrose 1 Milford, 1 Milton 1 New Bedford, 1 Salisbury 1 Somerville, 1 Waltham, 1 Wakefield, 1 West Springfield, 1 total, 32.

Tetanus was reported from Fall River 1 Worcester 1 total, 2.

Trachoma was reported from Watertown, 1 total 1

Trichinosis was reported from Newton 1 total, 1

Typhoid fever was reported from Framingham 1 Somerset, 1 Somerville, 7 Worcester 1 total, 10.

Undulant fever was reported from Ashburnham 1 Dedham 1 West Springfield 1 Worcester 1 total 4

Typhoid fever had its highest April incidence since 1935. A focus in Somerville accounts for the major part of this increase.

Bacillary dysentery primarily of the Sonne and Hiss-Y types, continues to be reported well above the five year average.

The reported incidence of chicken pox is slightly above the five year average.

German measles, measles, mumps and scarlet fever were reported well below the five year average.

Gonorrhea syphilis and meningococcus meningitis were reported at expected levels.

There was nothing remarkable in the reported incidences of anterior poliomyelitis, diphtheria lobar pneumonia, tuberculosis, whooping cough and undulant fever

NOTE

At the recent annual meeting of the American Laryngological Association, held at Harrison New York, Dr Gordon Berry of Worcester Massachusetts, was elected president and Dr Charles T. Porter of Boston, first vice president.

CORRESPONDENCE

GUAIKADYL

To the Editor During the past two years I have received numerous requests from physicians throughout New England for information regarding the product Guaiakodyl. These requests are based on the fact that the manufacturers of this product gave me a quantity to use in the Pulmonary Clinic at the Massachusetts General Hospital. I should like to state briefly the results of its use.

This material contains 0.05 gm. of guaiacol and 0.025 gm. of cecodylic acid per cubic centimeter of water. The total of approximately 500 cc. was given to a group of seven patients. The doses ranged from 1 to 4 cc. intramuscularly at intervals of one to three days. The largest amount to one patient was 138 cc. over a period of two months. Routine complete urine examinations were done frequently on all patients, and no difficulties were noted with the use of the product other than the complaint of transient dizziness which frequently followed the injections. No evidence of renal or skin irritation was noted. The patients all had bronchiectasis. There was no change in the course of the disease. The patients said that the material caused them no difficulty and all stated that the sputum was thinner and that they were able to raise it more easily while they were taking the medicine. The patient receiving the large dosage had extensive disease with multiple cavities and foul sputum. The foulness was converted to a creosote odor and both the patient and the family were convinced that the drug made things much more pleasant for all concerned. Guaiacol by mouth had caused a severe gastritis in this patient.

It seems that this product is harmless in the quantities used, and that it is a satisfactory expectorant and deodorant, particularly in a case with foul sputum. Through the manufacturers I have contacted a number of reliable physicians who have been using this product, and these doctors state that a total of approximately 5000 cc. of this material has been used by them without any ill-effects.

REPORTS OF MEETINGS

HARVARD CHAPTER OF NU SIGMA NU

At the Harvard Medical School on February 29 the Harvard Chapter of Nu Sigma Nu presented Dr. D. D. Van Slyke, of the Rockefeller Institute, New York City.

The speaker recounted physiological studies of the kidney which originated from an attempt to explain the mechanism that maintain the constancy of the urea clearance under conditions of varying blood concentration. In a normal man the kidneys excrete per minute the amount of urea contained in about 75 cc. of blood. The "urea clearance" is 75 cc. per minute. If the blood-urea concentration is doubled the excretion rate doubles, so that the kidneys still clear 75 cc. of blood per minute.

In experiments with dogs in which the renal veins were made accessible by Rhoads' "explanting" in operation, it was found that this constancy of the clearance in the presence of changing blood-urea concentration is due to the fact that the kidneys regularly remove from the renal blood a constant fraction, approximately one twelfth of the urea. This occurs whether the blood-urea concentration is high or low. Consequently if the renal blood flow is constant, the urea clearance remains constant. Va

riations in the clearance could be induced in dogs by varying their renal blood flow, but the fraction of urea removed remained the same. In man, if the kidneys, as in the dog, remove one twelfth of the urea from the renal blood, the average clearance of 75 cc. indicates a renal blood flow of 900 cc. per minute, and other data indicate that this is in fact about the rate of blood flow through human kidneys.

Under ordinary conditions, the urea clearance appears to vary in proportion to the renal blood flow. It falls when the renal blood falls, when, as in shock, blood is withdrawn from the peripheral circulation, or when, as in chronic nephritis, destruction of glomerular tissue cuts down the channels for renal blood flow. The clearance has been useful in following the progress of Bright's disease. When the urea clearance falls to 5 per cent of normal, and not until then, death in uremia is imminent. In acute nephritis the clearance may fall to 10 per cent of normal, and recovery still occur, if the clearance begins to rise within four months.

The extracted fraction of the urea in the renal blood does not appear, under all conditions, to remain constant at one twelfth. Smith and Goldring, estimating the renal blood flow in man from the Diodrast clearance, have found that under the influence of adrenalin and of certain other factors the clearance can undergo wide variations without variation of the renal blood flow. Under these conditions, the variations are due to changes in the extracted fraction. Smith and Goldring's explanation is that constriction and relaxation of the efferent glomerular arterioles occur under the influences mentioned, and thereby vary the blood pressure in the glomerular capillaries. As a result, parallel variations are caused in the proportion of plasma water which, according to the filtration-reabsorption theory, is filtered in the glomeruli. These variations in filtration compensate for changes in renal blood flow rate, and leave the clearance constant.

The theory of renal excretion mentioned accords with all the known facts of renal physiology, and aids in their comprehension, it was asserted. It is based on work by Cushny, Richards, Marshall, Smith, Shannon and others. According to it, as the blood perfuses the kidneys part of the plasma water is filtered into the glomerular capsules. Richards and his colleagues have collected the filtrate from individual glomeruli of frogs' kidneys, and have shown by ultramicroanalyses that it is a true plasma filtrate, containing all the filterable substances of the plasma in the same concentrations as those in the plasma.

The proportion of plasma water filtered was made the object of study in the speaker's laboratory by observations on dogs with kidneys explanted by Rhoads. It was found to average 20 per cent of the entire plasma water. With this water is filtered 20 per cent of the urea, uric acid, sugar and so forth dissolved in the plasma.

As the filtrate passes down the tubules the greater part of the water, an average of about 98 per cent in man, is reabsorbed into the blood. This reabsorption is necessary, for the volume of the glomerular filtrate formed in twenty-four hours by a man is calculated to be about 150,000 cc. This much has to be filtered to remove waste products at a physiological rate, but the water must be taken back or man in a dry environment would be in continual danger of death from desiccation.

With the water some of the dissolved substances of the glomerular filtrate are partly or completely reabsorbed. They may be divided into three groups: substances, like glucose, that the body needs to retain completely, and that are completely reabsorbed so that none escape in the urine; substances like sodium chloride, of which a certain amount needs to be retained in order to maintain physio-

logical composition of the body fluids—of these substances the renal tubules reabsorb what is needed, the excess passing into the urine, and substances that are merely excretory waste products, like urea and creatinine, and for which there is no physiological reason for reabsorbing. The tubules do not reabsorb these last substances actively, and in fact act as a barrier to their diffusion into the blood with the reabsorbed water. This barrier is not perfect, and some of the filtered urea and uric acid diffuse back, but the proportion is slight compared with that of the substances in the first two groups.

Dr. Van Slyke mentioned how the alkali reserve of the body is maintained by this process of selective reabsorption. The sodium bicarbonate that is filtered out in the glomeruli is almost completely reabsorbed in the tubules. Furthermore, ammonium bicarbonate is formed in the kidney and is apparently extruded into the proximal part of the tubule, then in the distal part a combined chemical and physiological reaction occurs whereby the ammonium bicarbonate combines with the sodium chloride filtered from the glomeruli, and sodium bicarbonate is reabsorbed while the ammonium chloride passes into the urine. The effect of this process is to replace blood sodium chloride with sodium bicarbonate. Simple reabsorption of filtered sodium bicarbonate, first mentioned, prevents loss of bicarbonate from the blood. But the replacement of sodium chloride by sodium bicarbonate through the above chain of events adds to the bicarbonate reserve of the body. Through this mechanism ammonia enables the body to restore its alkali reserve when it has been depleted by acidosis.

The speaker concluded that the filtration-reabsorption theory accords with what is known concerning the processes by which the kidneys prevent the escape of glucose into the urine, regulate the volume and electrolyte content of the body fluids, excrete waste products of metabolism and regulate the acid-base balance of the body.

BOOK REVIEWS

The Electrocardiogram and X-Ray Configuration of the Heart Arthur M. Master 222 pp. Philadelphia Lea & Febiger 1939 \$6.50.

Dr. Master has composed an atlas of electrocardiograms and x-ray pictures of the heart for beginners who have had their fundamental grounding in technique and principles. The volume may prove helpful even to those more skilled in cardiology since there are a number of points that the author emphasizes which are not kept constantly in mind or concerning which there have been advances. For example he calls attention to the fact that in a case of valvular heart disease the presence of high voltage without axis deviation usually indicates both left and right ventricular enlargement.

He explains the purpose of the book in the first two paragraphs of the preface as follows:

Excluding arrhythmias, electrocardiography may be divided into two parts, the changes associated with muscle damage, acute or chronic, and those related to the configuration of the cardiac chambers. Examples of the first group are rheumatic carditis, myocardial infarction and fibrosis, lobar pneumonia, typhoid fever, and acute nephritis. The second group includes factors such as age, body position, habitus, obesity, pregnancy, hypertension, valvular disease, congenital heart disease, pulmonary disease and deformities of the chest which alter the contour of the heart. The significance of the second group has been largely neglected, and this monograph has been written in the effort to correct this, since an appreciation of the dependence of the electrocardiogram on the size, shape and position of the heart is absolutely fundamental in the interpretation of the electrocardiogram.

The need for such a book is indicated particularly at the present time, since electrocardiographic instruments are now obtainable at quite low prices and the

technique of taking the record has become very simple. As a result a large number of physicians are now taking and interpreting electrocardiograms without the study and application necessary for doing this properly.

The contents include, after a short introduction, a brief statement about the normal electrocardiogram. Illustrations follow showing the effect of age on the contour and size of the heart and on the electrocardiogram, beginning with the newborn and proceeding to extreme old age. Next there is an important section on the effect of change with body position and respiration, and the relation of the x-ray plate and electrocardiogram to body habitus. These illustrations are perhaps the most important in the book for they are most often wrongly interpreted. There follows a discussion of axis deviation and ventricular preponderance, first of the left side of the heart secondary to hypertension and aortic valvular disease, and second of the right side of the heart secondary, chiefly, to mitral stenosis. There is a presentation of the effect of combined valvular disease of the heart and of symmetrical enlargement due to other causes, and a section on congenital heart disease. The last five sections deal with auricular enlargement, Graves's disease, pericardial effusion, pulmonary disease (with the acute and chronic cor pulmonale) and deformities of the chest.

The most difficult part of the book and that section which is the least well presented concerns congenital heart disease. One may raise a question about the interpretation of several of the cases, particularly Cases 51, 53 and 56. One also misses in the discussion of thyroid disease the characteristic x-ray picture and electrocardiogram of well marked myxedema. One may question the statement on page 96 that a slurring of the QRS group indicates myocardial involvement. Such slight slurring as is shown is consistent with marked enlargement of the heart, which may also account for increase in the width of QRS waves without the need of interpreting bundle branch block. This latter point Dr. Master emphasizes, on page 108, as an important and relatively new point of view, which he states that he will present in a further publication. The statement on page 160 that, in the case of the tetralogy of Fallot, right axis deviation is the result of the large right ventricle, whereas the increased amplitude of the QRS complex is probably caused by the enlarged left ventricle, is open to question, since in such cases the left ventricle is not enlarged and the increased amplitude of the QRS complexes is quite adequately explained by the very large right ventricle. There are two or three minor errors: on pages 28 and 29 left ventricular hypertrophy might be better expressed as left ventricular preponderance since the heart itself is stated to be normal, and on page 181 the word "restored" in the legend should be "absorbed."

One of the interesting aspects of the book is the inclusion of brief historical references. In the discussion of large P waves one might add on page 171 Samoiloff's name, since he contributed an important paper in 1909 on the large P waves of mitral stenosis.

There are two figures that are especially instructive in showing the evolution of the electrocardiogram. Figure 31, which shows the development of the hypertensive electrocardiogram, and Figure 38, which shows the development in both the electrocardiogram and roentgenogram of progressive enlargement of the left ventricle secondary to syphilitic aortic insufficiency.

The text of the book is clear and simple. The illustrations are clear cut and well arranged. The reviewer was at first disturbed by the fact that some of the

x-ray pictures were in different positions, even upside down, but such pictures were so arranged to indicate the position in which the person was lying at the time, showing the effect of change in position.

The plan of this book is novel and brings together more extensively than has been done before the combination of roentgenographic and electrocardiographic patterns in structural defects of the heart.

A Symposium on Cancer Given at an Institute on Cancer Conducted by the Medical School of the University of Wisconsin. 202 pp. Madison: University of Wisconsin Press, 1938. \$3.00.

This group of addresses given at the Institute on Cancer conducted by the Medical School of the University of Wisconsin in 1936 gives a considerable amount of interesting information. The material presented was new and of interest at that time, but the field has naturally progressed considerably in the past three and a half years.

There are two articles on experimental tumor production by Kreyberg, an excellent review of the value of tissue cultures in the study of cancer by Lewis and addresses on a number of other fields of cancer research that are sound but somewhat ephemeral in their interest. There would be some disagreement with Macklin's interpretation of the familial incidence of cancer. Likewise, some would question Coutard's estimate that 15 to 20 per cent of all breast cancers are extremely radio-sensitive.

A Mirror for Surgeons: Selected readings in surgery D'Arcy Power. 230 pp. Boston: Little, Brown & Co., 1939. \$2.00.

By training, temperament and experience, Sir D'Arcy Power—the dean of the British surgical profession, so referred to by Dr. Francis R. Packard, who writes the "Introduction"—is peculiarly qualified to present to the medical profession essays containing brief biographical notes and extracts from some of the writings of twenty-two surgeons. Perhaps the most satisfying compensation offered to the reader by these selected readings in surgery is the opportunity of following the evolution of surgical thinking, beginning with the quaint English of John Arderne in the fourteenth century. The surgeons considered are as follows: Thomas Gale, Ambrose Paré, John Halle, William Clowes, Maister Peter Lowe, John Woodall, Richard Wiseman, William Cheselden, Percival Pott, John Hunter, Abraham Colles, Sir Charles Bell, John Collins Warren, Sir Benjamin Collins Brodie, Sir James Paget, Lord Lister, Sir Jonathan Hutchinson, Sir William Macewen, William Stewart Halsted, Henry Jacob Bigelow and James Marion Sims. This book will find good service in all libraries.

Caesarean Section: Lower segment operation C. McIntosh Marshall. 230 pp. Baltimore: William Wood & Co., 1939. \$6.50.

This book is an interesting, careful monograph on the low segment method of cesarean section. It is well illustrated and clearly written, and there is an excellent bibliography after each chapter pertaining to the various parts of the operation. The author, however, has written nothing about postoperative treatment, a detail which, to the reviewer, is very necessary and important.

In the book sent for review there is an error in binding which, if it holds throughout the entire edition, is a very serious defect. The price of the book seems a little out of proportion to its value.

EXCESSIVE ACETYLTATION OF SULFANILAMIDE IN ADVANCED RENAL DISEASE*

Report of a Case

J GARROTT ALLEN, M.D.†

CHICAGO

MARSHALL, Emerson and Cutting¹ have shown in the human subject that more than 90 per cent of the quantity of sulfanilamide ingested is excreted by the kidneys. Stewart, Rourke and Allen² demonstrated that this drug is rapidly cleared from the blood stream in a manner similar to that of urea. From these two studies the clinical inference has been made that sulfanilamide should be used with caution in cases of impaired renal function. However, careful observations have not been made on human subjects concerning the excretion of this drug in cases of severe renal disease.

It is the purpose of this paper to report a case of duodenal ulcer with advanced renal disease in which sulfanilamide was given in the treatment of a wound infection. In this patient the blood concentration of both the free and the conjugated forms of sulfanilamide rapidly became excessive, although the quantity given was well within the limits of present usage. The accumulation of excessive acetylsulfanilamide has been reported in the nephrectomized rabbit.³ This phenomenon has not been reported in man. Since the acetylated portion of sulfanilamide is many times more toxic than the free form, it is possible that the excess of acetylsulfanilamide which occurred in this patient was a contributory cause of death.

CASE REPORT

A 59-year-old white, married bookkeeper was admitted to the University of Chicago Clinics on December 12, 1938 complaining of epigastric distress and vomiting following meals.

In 1935 an ulcer in the first portion of the duodenum had been demonstrated by fluoroscopic examination. The patient was at that time placed on careful ulcer manage-

ment including powders, but in spite of this regime the ulcer symptoms continued and between August, 1937 and May 1938 he experienced three bouts of hematemesis. About 2 months prior to admission symptoms of pyloric obstruction first appeared, and this diagnosis was confirmed by x-ray examination on admission.

For 7 years preceding 1937 the patient experienced increasing symptoms of urinary obstruction from benign prostatic hypertrophy. A transurethral electroresection was done on June 24, 1937 and relief of symptoms was obtained, although mild urinary frequency persisted. The nonprotein nitrogen at the time of operation was normal but the urine was heavily infected with colon bacilli. The postoperative course was otherwise uneventful.

On admission to the University Clinics a gastroenterostomy for relief of pyloric obstruction was advised. However because of moderate alkalosis and a severe reduction of urea clearance (Table I) surgery was delayed and the

ulcer powders which the patient had taken continuously for 2 months were discontinued. Sodium chloride in large quantities was given orally and parenterally but the response was slow and minimal. No further significant findings were observed and icterus was never present.

On the 28th hospital day a posterior gastroenterostomy was done. The early postoperative course was uneventful but on the 34th day a superficial wound abscess was found

From the Department of Surgery, University of Chicago. This work was aided by a grant from the Douglas Smith Foundation for Medical Research.

and drained. A mild elevation of temperature developed on the 39th day and continued through the 46th day. The patient was then afebrile until the 57th day, when temperature elevations to between 99.0 and 103.0°F gradually developed, although no satisfactory explanation for this fever was found. Blood cultures on the 43rd, 46th, 70th and 71st days showed no bacterial growth, and agglutination tests for typhoid, paratyphoid A and B and undulant fever bacilli and infectious mononucleosis were negative. The white-blood-cell count slowly rose to 20,000 by the 69th day.

Beginning on the 70th hospital day, sulfanilamide was given in doses of 15 gr (10 gm) every 4 hours for 3 days, making a total of 255 gr (165 gm.) On the morning of the 73rd day the patient was somewhat stuporous, so sulfanilamide was discontinued. Blood was drawn for chemical studies and a free sulfanilamide blood level of 28 mg per 100 cc. was noted (Table 2). On the 74th day

the free blood sulfanilamide was 19.8 mg per 100 cc., while the total, including the combined form, was 37.8 mg. Both forms slowly fell, and on the 77th hospital day the acetylsulfanilamide blood level was 12.9 mg per 100 cc., while the free level was only 1.2 mg, resulting in a total of 14.1 mg. The blood chlorides, calcium, phosphorus and nonprotein nitrogen were normal, although the blood carbon-dioxide content was slightly reduced. Complete urinary collections were begun on the 74th hospital day by means of an indwelling catheter, and daily samples were analyzed for their sulfanilamide content (Table 2). Large amounts of fluids were given parenterally in hope of producing a diuresis to facilitate sulfanilamide excretion. However, the patient's urinary volume gradually decreased, and he became anuric during the last 18 hours of life. He died on the 77th hospital day in respiratory failure.

At autopsy the recent midline abdominal scar contained the opening of a small sinus in its upper third, from which about five drops of pus were expressed. This sinus ended blindly in a mass of scar tissue on the anterior surface of the duodenum. There were numerous adhesions in the abdominal cavity between the liver, the stomach, the duodenum and the anterior abdominal wall, although no free fluid or abscesses were found. The stoma of the gastro-enterostomy was patent and competent. The ulcer on the posterior wall of the duodenum gave evidence of healing, there were no signs of recent bleeding or perforation, although a high grade of stenosis was present in the first portion of the duodenum. The kidneys were small and pale, their combined weight being 165 gm. Their capsules stripped with ease from smooth, pale surfaces. The cortical markings were obscure. The pelvic fat was increased, and each renal pelvis was dilated and thick-walled. The calyces were large and clubbed at their ends. The urinary bladder was contracted and thick-walled, and the prostate was small. Except for several small areas of consolidation at the right base the lungs and heart were normal. One

of the three parathyroid glands found was definitely enlarged. There were numerous areas of fibrocystic disease in the skeleton. The microscopic studies added little. In the kidneys there was destruction of most of the tubules and many of the glomeruli, with deposits of calcium in some of the tubules, and from the gross and microscopic findings the diagnosis of a chronic ascending nephritis was made. The evidence of hyperplasia of one of the parathyroid glands was confirmed by microscopic section.

DISCUSSION

Since the excretion of sulfanilamide by the kidneys is quite similar to the excretion of urea, it is presumable that any renal damage sufficient to impair the clearance of urea might also effect the clearance of sulfanilamide. Furthermore, as the kidneys represent the sole important channel of escape of this drug, any delay in the renal excretion of sulfanilamide would allow it to accumulate in the blood stream. In the case presented here a severe reduction of urea clearance had been demonstrated (Table 1), and this functional impairment is attributed to a chronic ascending nephritis, plus the effect on the kidneys of a prolonged period of alkalosis. Under these conditions a high grade of retention of sulfanilamide resulted, which in turn gave rise to excessive blood concentrations of this drug. Such a high sulfanilamide blood level may also be produced by giving excessive quantities of the drug, but in this case, since the dose did not exceed present practice, all evidence points toward delayed excretion as the cause of this abnormally high concentration.

It is very interesting to note that most of the sulfanilamide retained was rapidly conjugated into the acetyl form at the expense of the free sulfanilamide, which practically disappeared from the circulating blood. Twenty-four hours after the drug was discontinued a total blood level of 37.8 mg per 100 cc was present, and of this quantity 18 mg, or 47 per cent of all the circulating sulfanilamide, was conjugated. This percentage slowly increased until twelve hours before death, when more than 90 per cent of the remaining drug was in acetyl form. There was, of course, a slow quantitative decline commensurate with the retarded renal loss. Such a high percentage of the drug appearing in the conjugated form is not ordinarily seen in patients receiving sulfanilamide. However, Stewart, Rourke and Allen³ have reported a similar, abnormally high percentage of acetylsulfanilamide in the rabbit when excretion of the drug was prevented by nephrectomy. In this animal the site of conjugation is in the liver. These workers showed that the process of acetylation, which continues at a relatively constant rate in the nephrectomized rabbit, gradually results in the

complete acetylation of a given amount of sulfanilamide in two or three days. Consequently, the unusually high percentage of acetylsulfanilamide present in the case here discussed suggests that in the human subject conjugation also progresses at a relatively fixed rate unrelated to renal function, and that when a given amount of sulfanilamide is retained in the circulatory blood for a period of time longer than normal, a greater proportion of drug becomes acetylated.

The significance of acetylsulfanilamide in man is not clearly understood. However, Marshall, Cutung and Emerson⁴ produced severe toxic symptoms in the rabbit when the acetyl form exceeded 7 to 9 mg per 100 cc., but untoward symptoms were not manifested when free sulfanilamide was given until a blood concentration of more than 40 mg was obtained. These workers suggest that many of the gastrointestinal and cerebral symptoms occurring in man may be associated with an increased amount of circulating acetylsulfanilamide. Therefore, in cases of renal disease where delayed excretion may lead to excessive quantities of conjugated sulfanilamide, the toxicity of the drug may be considerably increased, so that until further clinical knowledge is available sulfanilamide should be used with great caution in cases

in which delayed excretion of the drug may occur. In this case it was impossible to assign a cause of death. Since the brain was not examined, death from cerebrospinal disease cannot be excluded, but the presence of such large amounts of free sulfanilamide and acetylsulfanilamide in the blood stream may have been contributory in the cause of death.

SUMMARY

A case of duodenal ulcer and unexplained fever with severe renal disease is presented in which excessive blood levels of free sulfanilamide and acetylsulfanilamide were obtained although the quantity of the drug given was not excessive.

The abnormally high percentage of acetylsulfanilamide and its association with delayed excretion of the drug are discussed.

The importance of cautious administration of sulfanilamide to patients with renal disease is emphasized.

THE USE OF CIRCULATION TIME DETERMINATIONS IN THE DIAGNOSIS OF VENOUS-ARTERIAL SHUNTS*

ELTON YASUNA M.D.,† and SAMUEL KOWAL M.D.‡

BOSTON

IN THE study and diagnosis of heart disease the determination of circulation time may be a definite aid to the clinician and in some cases, as we shall point out later, may be as valuable as the stethoscope, sphygmomanometer, roentgenogram or electrocardiogram.

Normally the arm-to-lung circulation time that is, the time needed for the blood to travel from the antecubital vein through the right side of the heart to the lungs, is four to eight seconds¹⁻⁴. The arm-to-tongue time is ten to sixteen seconds^{1, 5, 6, 7}. In this interval the blood travels to the lungs as previously, but in addition must return to the left side of the heart and finally go to the taste buds of the tongue.

Hemodynamic changes in cardiac disease fre-

quently affect the velocity of blood flow, which in turn results in abnormal circulation-time determinations. Cardiac disease may cause a prolongation of circulation time (decrease in blood velocity) an acceleration of circulation time (increase in blood velocity) or no change.

Circulation time determinations have been found useful in studying the hemodynamics of early congestive heart failure.⁸ Blumgart and Weiss⁹⁻¹¹ have shown that a prolonged circulation time frequently precedes the clinical signs of cardiac failure such as edema, rales in the lungs, cyanosis and distended veins. Although congestive heart failure is the most frequent cause of prolonged circulation time this finding has also been noted in idiopathic and secondary polycythemia, and in hypothyroid states and other conditions causing a decrease in body metabolism.¹²

The diagnosis of heart disease produced by avitaminosis B₁ is facilitated by the presence of an

‡Instructor in medicine, Boston University School of Medicine.

accelerated circulation time¹³ An accelerated circulation time is also found in anemia, hyperpyrexia¹⁴ and cardiac conditions associated with hyperthyroidism^{12 15}

Another clinical use of circulation time is in differentiating cardiac and noncardiac conditions, as, for example, in distinguishing between cardiac and bronchial asthma In the former the circulation time is prolonged, while in the latter it is normal Still another possible application of these tests is to demonstrate certain cardiac malformations, congenital or acquired, and it is this use that we shall discuss more fully

In a venous-arterial shunt there is a direct mixing of unoxygenated or venous blood with oxygenated or arterial blood Clinical examples of this condition are seen in congenital or acquired interventricular septal defects with right-sided cardiac hypertrophy, three-chambered hearts, transposition of the aorta, anomalies of blood vessels and so forth In these cases the patient is cyanotic at all times

The arm-to-lung circulation time in a venous-arterial shunt is normal, since the blood goes on its regular route from the arm to the right side of the heart and to the lungs The arm-to-tongue time, however, is lessened, because a certain percentage of blood, after traveling from the arm to the right side of the heart, is shunted to the left side through the existing anomaly or defect, avoiding the pulmonary circulation entirely and continuing on to the tongue The pulmonary circulation is short-circuited in this course, thus reducing the duration of arm-to-tongue time Since the time needed for the blood to travel from the arm to the right side of the heart and to the lungs (arm-to-lung time) is about the same as the time needed to travel from the arm to the right side of the heart, to the left side (through defect) and to the tongue (arm-to-tongue time), one should find the two times about the same in a case of venous-arterial shunt

With this principle in mind, as first pointed out by Benenson and Hitzig¹⁶ at Mt Sinai Hospital in New York City, circulation-time determinations were performed in the following case, one of tetralogy of Fallot—interventricular septal defect, pulmonary artery stenosis, right ventricular enlargement and transposition of the great vessels as they emerge from the heart

CASE REPORT

R. M., a 19-year-old Italian born white girl, was admitted to the Boston City Hospital on January 17, 1939, complaining of fatigue of many years' duration and of a generalized cyanosis, especially marked on the face and extremities

In November, 1938, she had been on another service of the hospital for the same complaints

Eleven years previously the patient had been told that she had "rheumatic heart disease." The chief complaints at that time were weakness, fatigue and failure to gain weight, and these symptoms had continued to the present, associated with occasional palpitation of the heart. She was always up and around, however, except for the year previous to entry, when her fatigue became so marked that she voluntarily stayed in bed When the fatigue was most marked the persistent cyanosis became more intense and the extremities felt cold The patient had moderate dyspnea on exertion and was more comfortable in the upright position. Nocturia—two or three times—had been present during the month previous to admission, and the menses, which had started at the age of fourteen, were scant and irregular There was no history of joint, muscle or chest pain, sore throat, chorea, fever, night sweats, epistaxis or edema

Physical examination revealed a poorly nourished, under developed white girl, moderately fatigued and orthopneic but not acutely ill The skin was bluish scarlet, especially over the nose, cheeks and extremities The head, neck and lungs were normal The chest wall had a moderate *Trichterbrust* deformity The apex beat of the heart was sharply felt in the fifth interspace, 7.5 cm from the mid-sternal line. The rate was 130 per minute and regular A systolic thrill was palpable over the pulmonic area. A loud, harsh systolic murmur was heard over the third and fourth interspaces to the left of the sternum, and was transmitted toward the left axilla The second pulmonic sound was markedly accentuated The extremities were cyanotic, felt very cold and showed clubbing of the fingers and toes The remainder of the examination was normal.

The red blood-cell count varied between 7,210,000 and 8,890,000, and the hemoglobin between 20.0 and 25.4 gm. (Sahli) per 100 cc. The white-cell count was 16,900 with 76 per cent polymorphonuclear leukocytes and 24 per cent lymphocytes Several specimens of urine were negative except for an occasional white cell per high power field. Repeated stool examinations were negative for occult blood. A blood Hinton test was negative. The blood pressure was 118/88 in both arms Electrocardiographic tracings showed a right axis deviation at all times, and 7 foot roentgenograms of the heart revealed a constant accentuation of the pulmonary conus

The arm-to-lung circulation time (normal, 4 to 8 seconds) was determined by the use of 5 minims of ether diluted with an equal amount of physiological saline solution, the time being recorded from the injection of the ether to the moment the patient smelled it. Paraldehyde in similar dosage and dilution was also used for measuring the arm-to-lung time. The ether times were 8.1 and 8.2 seconds, while the paraldehyde times were 8.1 and 8.6 seconds. No systemic vascular reaction was experienced.

Arm-to-tongue circulation time (normal, 8 to 16 seconds) was determined by the injection of 5 cc. of Decholin (dehydrocholic acid) solution, and also of 5 cc. of calcium gluconate solution The patient indicated the moment she tasted the substances The calcium gluconate times were 8.4 and 9.2 seconds, and both Decholin times were 8.0 seconds

Each determination of arm-to-lung and arm-to-tongue time was repeated at least four times, and reasonable checks were obtained Interspersed among the actual tests, physiological saline solution alone was injected intravenously on two occasions, the patient being requested to indicate the end point, no taste or smell sensations were noted.

Observations were made on various days. On all occasions the patient was co-operative, alert and intelligent making us feel confident in the results.

The arm-to-lung and arm-to-tongue circulation times were practically identical the respective averages being 8.3 and 8.4 seconds. We believe this similarity in results to be due to a functioning venous-arterial connection as discussed earlier in this paper. The arm-to-lung circulation time determinations of 8.1 to 8.6 seconds are slightly above the accepted normal upper limit of 8 seconds. This finding is readily explained by the secondary polycythemia present in this case.

Benenson and Hitzig's¹⁶ results in 2 cases of tetralogy of Fallot, with ether and saccharin as test agents, were similar to ours. In one case the arm-to-lung time was 11.0 seconds, and the arm-to-tongue time 11.8 seconds, in the other case the times were 7.5 seconds and 3 to 4 seconds respectively. McGuire and Goldman¹⁷ observed accelerated arm-to-carotid sinus times (3.8-4.8 and 4.0 seconds respectively) with the use of sodium cyanide in 3 cases of tetralogy of Fallot but they did not make arm-to-lung time determinations. Several conditions may cause an accelerated arm-to-tongue (or arm-to-carotid sinus) circulation time. The diagnostic value of circulation time determinations does not lie in any change in arm-to-lung or arm-to-tongue time, but in the finding of similarity between them.

SUMMARY

Circulation time studies were performed in a case of venous-arterial shunt (tetralogy of Fallot)

The arm-to-lung and arm-to-tongue circulation times were found to be similar.

This result can be utilized to establish the diagnosis of venous-arterial shunt.

CLINICAL NOTE

PNEUMOPERITONEUM DUE TO PERFORATION OF THE TRANSVERSE COLON IN AN UMBILICAL HERNIA

Report of a Case

FRANKLIN G. BALCH, JR., M.D.*

BOSTON

PNEMOPERITONEUM from perforation of an ulcer of the intestinal tract, particularly in

in industry where the bowel is forcefully distended with air via the rectum¹⁻³ Examination of the literature, however, reveals no report of pneumoperitoneum from causes as presented in the following case, and it would therefore seem of interest to report this case in some detail

CASE REPORT

The patient, R. M., was a 69 year-old German housewife. Her past history was irrelevant. She had always been healthy until 1 hour before being seen, when she had a sudden chill with pain in the right upper quadrant of the abdomen, associated with nausea and marked cyanosis.

FIGURE 1

the duodenum, is not uncommon. This same condition has also been reported from traumatic rupture of the bowel from the use of compressed air

She complained of severe general abdominal pain and difficulty in breathing. She looked extremely sick. There was deep cyanosis. The abdomen was markedly distended and tender throughout, with the maximum point of tenderness in the right lower quadrant. There was an umbilical hernia about 7 cm. in diameter which contained

*Assistant in surgery Harvard Medical School surgeon Faulkner Hospital

no viscera but free gas which could be readily expressed. There was complete obliteration of liver dullness. The pulse was 96 regular and of good quality the blood pressure was 112/80. The patient was sent at once to the hospital, where Wangenstein drainage of the stomach was instituted, without relief of the distention. X-ray films of the lower thorax and abdomen taken with the patient semi-upright showed marked elevation of both leaves of the diaphragm due to a pneumoperitoneum there was a single tremendously dilated loop of large bowel in the right flank (Fig 1).

Under novocain infiltration and cyclopropane anesthesia a laparotomy was performed through a right rectus muscle splitting incision. When the peritoneum was opened a large amount of foul-smelling gas escaped with immediate decompression of the abdominal wall. The cecum was tremendously dilated, but no perforation was found at this point. No bowel was protruding into the umbilical hernia. There was diffuse peritonitis along the course of the cecum and ascending colon but no fecal matter was found free in the peritoneal cavity. The incision was extended upward and an area of necrosis was found in the transverse colon about 3 cm. in diameter lying 3 cm. medial to the hepatic flexure. The bowel was not strangulated but there was a minute perforation in the middle of the necrotic area. The hepatic flexure was freed so that the necrotic area of bowel could be exteriorized, suturing the bowel

together as in a Mikulicz type of operation. A Mixer tube was then inserted at the site of perforation. No effort was made to drain the abdominal cavity.

The patient had two chills on the 1st and 2nd days following operation with a fall in temperature to normal on the 7th day. The colostomy opening drained well. The Mixer tube sloughed out spontaneously in 5 days. Clamps were applied on the 12th day after operation. Phlebitis developed in the right leg but subsided in 10 days. Three weeks after the operation the patient was having excellent bowel movements by rectum and there was very little drainage from the operative site. Shortly after this a polyp protruded from the rectum with each defecation. This was removed 5 weeks after the first operation. The patient made an entirely uneventful convalescence from this operation and was discharged 69 days after entry at which time the colostomy opening was almost entirely healed.

Three months after discharge the patient died at home from a cerebral hemorrhage. No autopsy could be obtained.

REPORT ON MEDICAL PROGRESS

DIAGNOSTIC ROENTGENOLOGY

RICHARD SCHATZKI, M.D.*

BOSTON

IN THE progress report¹ of last year emphasis was laid upon a description of the general trends which have characterized the development of diagnostic roentgenology in recent years. This year a few specific diagnostic problems have been selected for discussion, the choice being based in part on the fact that the articles in question have described something new, in part on the opinion of the reviewer that the particular subject has enough everyday importance to warrant the discussion of its present status.

ROENTGEN EXAMINATION IN PATIENTS WITH ILEUS

Recent developments in the diagnosis and treatment of ileus have influenced the work of roentgenological departments.

Roentgenology has been used for many years as an aid in establishing the diagnosis, localization and progress of the disease process in patients with ileus. Case² was one of the first to emphasize

the importance of the flat (scout) film of the abdomen for these purposes. Such films have become a routine procedure, since they represent "the most important single objective finding in the patient with small-bowel obstruction"³ in particular, and of any kind of ileus in general. They usually establish the diagnosis of ileus, positive findings being more conclusive than negative ones. If there is obstruction in the colon such films often allow a differentiation from paralytic ileus whereas the distinction between mechanical and paralytic ileus is usually not possible in cases of obstruction within the small bowel or at the ileocecal valve. Not infrequently a localization of the point of obstruction is possible especially in the colon. A barium-enema examination may be necessary to differentiate a large atonic colon without obstruction from a case of low large-bowel obstruction. In addition it will in most cases define the etiology of the obstruction.

The enthusiasm which has developed for study and treatment of small-bowel disease in the last

*Instructor in roentgenology, Harvard Medical School; roentgenologist, Massachusetts General Hospital, Boston.

few years has been due to the introduction of the Miller-Abbott tube,⁴ by which the distended loops of small bowel can be deflated and investigated. For many years Wangensteen⁵ has emphasized the importance of deflation in the treatment of ileus, and constant suction through gastric or duodenal tubes has become common practice for this purpose. The Miller-Abbott tube with its two channels—one for suction, the other for the inflation of a balloon close to the end of the tube—has the advantage that it can be introduced into the small intestine, where it is then propelled by peristalsis until it stops at the point of obstruction. The tube was originally used for physiological studies, then for deflation in ileus, later in the localization of obstructive lesions and finally in the demonstration of the obstructing lesion and its character.⁶

Abbott⁷ characterizes the beneficial effects of intubation as follows: emptying of the intestine and restoration of the peristalsis, supplying data for adjustment of the fluid and electrolyte balance of the body, relieving the obstruction itself, identifying the location and nature of the lesion, simplifying the technic of any required surgical procedure, protecting the suture lines after operation, and converting an emergency into an elective surgical procedure.

The application of the tube requires some training and experience, so that disappointment not infrequently attends the first attempts at using it. The necessity of close, patient co-operation between surgeon and roentgenologist is stressed by those experienced in its use.

What is the role of the roentgenologist in this combination? It can be divided into two parts, one before and one after the tube has reached the point of obstruction. The most valuable help the roentgenologist can give in the first part of the examination is in guiding the tube through the pylorus. This is the most difficult part of the procedure. Failures of the method have usually been due to the impossibility of getting the tube into the duodenum, therefore, if possible, this part of the examination should be done under fluoroscopic control. The tube may roll up in the stomach, in which case it should be withdrawn to a proper length. The tip of the tube must be guided toward the pylorus and at times may be massaged into the duodenum. A drink of cold water, as recommended by Holmes, is of advantage in opening the pylorus. After the tube has passed the pylorus and the balloon is inflated, follow-up films may be taken at intervals of twelve to twenty-four hours

with a bedside unit to control the progress of the tube and check the degree of deflation taking place proximal to the balloon.

If the tube is used for deflation only, the main part of the roentgenological examination ends after the tube has stopped progressing and complete deflation has taken place. In other cases it is desirable to use the tube to investigate the area of obstruction. This may be done with a small amount of barium injected into the suction channel of the tube after deflation of the balloon. Several authors have reported good results with this method, which should be done under fluoroscopic control and preferably with the use of spot films.^{8, 9} In paralytic ileus the absence of obstruction can be demonstrated, and in mechanical ileus the exact location and character of the obstructing lesion can be visualized. A differentiation between obstruction due to neoplasm, inflammation or adhesive bands is usually possible.⁹ Lofstrom and Noer⁸ enumerate the advantages of this type of barium examination as follows: only small amounts of barium are necessary, the barium is not diluted by secretions, these having been aspirated, the method is not dangerous, and most of the barium can be aspirated at the end of the examination.

Lofstrom and Noer have also recommended the Miller-Abbott tube for the examination of an isolated loop of small intestine in cases without obstruction. For this purpose the holes in the tube distal to the balloon are omitted, and the balloon instead of being deflated is inflated before the barium is injected. By this "segmental survey," which can be improved by using a tube with three channels and two balloons, any desired degree of barium filling is possible in any part of the small intestine. This is an ideal method of examining this portion of the intestinal tract, and is useful in certain cases. It is time-consuming, and, unless combined with a preceding routine examination which localizes the questionable lesion, not without danger for patient and doctor, owing to the amount of radiation which both may receive.

PREPYLORIC ULCER

The aim of roentgenology, and of gastrointestinal roentgenology in particular, is to demonstrate accurately the gross pathologic appearance of the lesion. By means of careful fluoroscopic studies, palpation, spot films, and profile and relief pictures of the lesion and its surroundings, the appearance of the lesion as it would be seen from the inside of the intestine can usually be well visualized. For this reason the roentgenological diagnosis of cancer of the stomach, particularly

ulcerated cancer, is fairly easy in most cases, just as it is for the pathologist when he inspects the opened specimen

The situation of the roentgenologist is different in those cases in which gross inspection of an ulcerated gastric lesion does not allow the pathologist to differentiate benign and malignant ulcer—lesions in which the microscopic examination determines the final verdict. It is obvious that no macroscopic examination including roentgenograms, will provide a diagnosis in such a case.

A number of authors have stressed the fact that these malignant ulcers (grossly benign but microscopically malignant) are particularly common in the prepyloric region. Several years ago Hampton¹⁰ reviewed the operative and autopsy findings as well as the postoperative follow up on patients with chronic prepyloric ulcerations. The prepyloric region was defined as an area 2.5 cm. long, immediately proximal to but excluding the pylorus. The center of the ulcer was taken as its origin and its distance from the pylorus then determined the classification of the ulcer within or without the group in question. Included in this study were all ulcerations in the prepyloric area which roentgenologically showed evidence of induration, that is, of chronicity, but which failed to show an obvious cancerous growth surrounding the ulceration. In other words, these cases had all the roentgenological criteria which were thought to characterize benign peptic ulcers of the stomach. Eighteen of the ulcerations were found to be cancerous histologically, though many of the lesions appeared benign at the gross inspection of the opened specimen. Only two ulcerations were found in this series which on serial sectioning proved to be benign. Eight additional cases were quoted from the old records of the Massachusetts General Hospital in which the operative findings were thought to indicate a benign prepyloric ulcer, hence a resection was not performed but the follow up later proved the cases to have been carcinomatous in nature. In other words, these studies showed that, excluding the obvious ulcerated prepyloric cancers, it was impossible to decide roentgenologically, or by any other method short of serial histological studies, whether an indurated ulcer in the prepyloric area was benign or malignant, but that the chance of its being malignant was very high.

Using similar but not identical criteria for defining the group of cases, Singleton¹¹ found a higher incidence of benignity, namely, seven benign to four malignant ulcers. He believed that a careful follow up of ulcerations in the prepyloric area would usually allow a roentgenological statement

in regard to benignity or malignancy although he admitted that a malignant ulcer might decrease in size or even disappear under medical treatment.

Another paper on this subject (that of Sampson and Sosman¹²) appeared within the last year and confirmed Hampton's conclusions. Among the cases quoted in this paper one is of particular interest in regard to the necessity of a complete pathological examination. An ulcer in the antrum but not strictly in the prepyloric area had been excised. The anatomical diagnosis was "Chronic gastric ulcer—no evidence of tumor." The patient returned to the hospital six years later with a frank gastric carcinoma. The original specimen being still available, new sections were made which showed the presence of cancer cells similar to those of the tumor removed at the second operation. The authors concluded:

1. Chronic ulcers in the prepyloric inch of the stomach are found to be cancerous in 75 per cent of our cases. It may be necessary to cut many histological sections through the excised ulcer to find the area of carcinoma.

2. These small prepyloric ulcers defy differential diagnosis by all methods of examination except histological and even the pathologists have erred in some of them.

3. Proved cases of prepyloric malignant ulcers are herewith reported: (a) in young persons, (b) with high gastric acidity, (c) with clinical improvement under ulcer therapy, (d) with decrease in the size of the ulcer under alkaline therapy and (e) with roentgen findings simulating benign ulcers.

4. We believe that prepyloric ulcers which do not disappear entirely in a few weeks should be treated by radical resection and even those that disappear should be carefully followed and re-examined periodically.

Studies such as these should not be considered as diagnostic short cuts. They do not relieve the roentgenologist of the necessity of studying a questionable lesion in the prepyloric area with meticulous care. In most cases of cancer, he will be able to recognize grossly the malignant character of the lesion. There remain however those cases of indurated ulceration in which a gross differentiation of benign and malignant ulcer is not possible. Benign ulcers do occur in the prepyloric region but they represent a comparatively small minority. The question of whether or not the rather small risk of a gastric resection is larger than the great risk of neglecting a gastric cancer is a clinical one which has to be answered from case to case.

ROENTGENOLOGICAL EXAMINATION OF THE PLACENTA

In last year's progress report¹ attention was called to a method which demonstrates placenta previa by the increase in the normal distance between the

fetal head and the urinary bladder filled with a contrast substance

Snow and Rosensohn¹³ and Brown and Dippel¹¹ in a confirmatory report have shown that it is possible to visualize the placenta directly. This is particularly true in those cases where it, as usual, does not lie in the pelvis. On good roentgenograms made without the use of any contrast substance the placenta can be seen as a localized bulge in the soft-tissue shadow of the uterine wall. It has a characteristic shape, and is usually clearly differentiated from other tissues by the subcutaneous fat layer of the adjacent fetus. Since the placenta commonly lies on the anterior or the posterior wall of the uterus, a lateral view is usually more successful, though both lateral and anteroposterior views should be taken. The presence of placenta previa can be excluded if the placental shadow is demonstrated in the fundus of the uterus. On the other hand, absence of demonstrable placental shadow is suggestive of placenta previa. This diagnosis may be confirmed by the injection of air into the bladder (Snow and Rosensohn, as well as Brown and Dippel, prefer the injection of 150 cc of air to that of radio-opaque substances, using it as a routine procedure). Placental apoplexy (premature separation), polyhydramnios and extrauterine pregnancy have been diagnosed on the soft-tissue films.

These studies represent a definite advance, especially in the cases of bleeding of unknown origin during pregnancy. Seen from a broader viewpoint, they are another application of soft-tissue roentgenology, a branch of roentgenology still in its infancy.

FATIGUE FRACTURES, WEAR-AND-TEAR FRACTURES, PSEUDOFRACTURES

A number of reports have been published in recent years concerning peculiar "fractures" of various bones, but especially of the tibia. In these cases a thin fracture line may be seen running usually straight across the bone, surrounded by a bandlike zone of increased bone density. The appearance of the dense zone may even precede the demonstration of the fracture line. There is usually local pain and tenderness, but no deformity. A single trauma does not seem to play any role in the history. The appearance of the lesion is very characteristic, inasmuch as it is usually seen in very definite regions. For example, in the tibia it occurs at the junction of the proximal and second quarters of the bone. Roberts and Vogt,¹⁵ who published a report of 12 cases observed in the tibia, described the characteristic clinical course and the roentgenological appearance of the lesions. They believe that the exact nature of the condition is

not known, but conjecture that it may possibly be due to chronic infection, perhaps influenced by the course of nutrient vessels, rather than to fracture.

These "fractures" are not confined to children. Reports from Finland and Germany¹⁶⁻¹⁸ indicate that they are not rare in soldiers, in whom the clinical picture is similar to that seen in children. These authors conclude that the lesion represents a chronic fracture, produced by repeated stress bearing upon the same spot in unprepared, untrained and possibly deficient bone. They compare such fractures to the fatigue breaks which occur in metal as a result of constant vibration or repeated bending back and forth.

These lesions are believed to represent only a special type within a large group of similar fractures, of which the so-called "march fracture" of the metatarsals is the commonest and best-known example. Other less common sites are the fibular shaft, the femoral neck, the medial portion of the upper femoral shaft, the inferior ramus of the pubic bone and the os calcis. Fracture of the first rib occurring in untrained persons who are forced to carry heavy loads on their shoulders has been explained on a similar basis.¹⁹ The so-called "navvy's" or shoveler's fracture,²⁰ a peculiar type involving the tips of the first dorsal and seventh cervical vertebrae, which occurs in poorly trained persons compelled to do hard labor, especially with pick and shovel, is thought to be due to the chronic trauma of constant muscle pull. In keeping with this explanation, the first symptoms in most cases do not appear until several weeks of hard labor have elapsed, indicating that repeated rather than single trauma is causatively concerned.

Fine fracture lines which occasionally occur in great numbers in a bone with Paget's disease, as well as transverse lines of decreased density in osteomalacic bones, are thought to be due to a similar mechanism. In these cases the diseased bone is not adequate for the stress of normal activity.¹⁷

All these processes are obviously of great theoretical interest, but their recognition is also of practical moment in regard to proper diagnosis, prognosis and treatment. In this connection I have seen a case of chronic fracture of the tibia with marked bone condensation in an adolescent in whom the diagnosis of Ewing's tumor was erroneously made and amputation advised.

SCREEN PHOTOGRAPHY

The idea of obtaining roentgenograms by using an ordinary camera to photograph the image on

the fluoroscopic screen goes back to the years immediately following Roentgen's discovery. Caldwell, among others, spent considerable effort on developing this method, but not until marked improvements had been made in the construction of fluoroscopic screens, x-ray tubes, photographic lenses and films did it attain any practical importance.

Advantages which the photographing of the fluoroscopic screen image offers in comparison to large-film radiography are several. On account of its smaller size the photographic film is less expensive. It is also more convenient if a large number of films of various persons are to be taken in rapid succession. The storage of such films is easier and less expensive than that of the usual sized roentgenograms. In other words, there would be a large field for screen photography provided the quality of the pictures were comparable to that of routine direct roentgenograms.

The principle of the apparatus used by the various investigators is similar. A small photographic camera, usually of the Leica type is firmly attached to the fluoroscopic screen at a certain distance. Most authors use a film 24 by 36 mm in size while a few use larger sizes (75 by 75 mm or 4 by 5 in.) An f1.5 lens is used in most cases.

The advantages of screen photography are particularly obvious in the routine serial examination of large groups, such as students, employees, soldiers, tuberculous suspects and so forth. De Abreu²² in Brazil, was the first to use this method for such purposes. Janker²³ deserves credit for several technical developments. The enthusiasm of these men and others has stimulated the extensive use and development of this method for serial examinations in a number of countries, particularly Brazil, Argentina, Uruguay, Germany and to lesser degree France and Italy. So far, the use of the method in the United States has remained limited. A few papers on the subject have appeared within the last year. Landberg,²⁴ Potter, Douglas and Burkelo²⁵ and Hirsch.²⁶

A well-organized set up is important for the rapid and efficient functioning of serial examinations. De Abreu advocates the creation of centers for complete thoracic surveys, using photographic installations in each of them. He believes that one million examinations could be done in such a centre in one year, thus making it possible to examine the total population of large cities initially and at routine intervals. Transportable machines have been constructed in Germany²⁷ and with military help an organization has been created which is rather interesting, though its applicability outside of Germany is for many reasons unlikely. The or-

ganization is divided into two branches, one stationary and one motorized. The stationary division supervises the operation of the project, processes the films and makes enlargements when necessary. The motorized division moves from town to town and sets up the equipment two or three times a day. The population is arranged according to size and is then conducted to the fluoroscopic screen. Instructions as to how to behave in front of the screen are issued to the first few subjects, and the rest are asked to imitate these. An automatic phonograph for giving the commands in regard to breathing has even been advised.²⁸ Each person holds in his hand a small card containing the necessary personal data, which is photographed together with the chest. A single machine is reported to be able to examine from four hundred to six hundred persons in one hour. For interpretation the film is magnified by means of a small projection lamp to an area about 10 cm square. One picture after another passes in rapid succession in front of the interpreter, who either dictates a very short report or — by simply placing an always ready sheet of photographic paper on the viewing area — makes a photographic copy of the projected enlargement for further study.²⁹ It is said to be easy for a trained examiner to read five hundred films in one hour especially if most of the patients are healthy, for example, soldiers. The number is smaller if less healthy persons are examined, for example, factory workmen.²⁷ Data thus obtained are stored in central files.

The main importance of such serial examinations is believed to lie in the ability to recognize all cases of tuberculosis. Some authors^{27, 29} have compared a large series of fluoroscopic screen photographs with routine full sized roentgenograms of the same patients, and concluded that active tuberculous processes were diagnosed from the screen photographs in almost all cases. This finding is rather unexpected when all authors admit that the detail and contrast of the screen photographs are definitely inferior to those of the routine roentgen films.* It is thought, however, that the examination represents only an extensive filter which helps to discover grossly diseased as well as possibly diseased persons. The qualitative diagnosis can be made only by clinical examination together with a large routine roentgenogram which should be taken in every case in which disease is found on the screen photographs.

In other words screen photography as yet does not equal the routine roentgen examination, which

*The definition on the far left of 3 photographic films, 75 by 75 mm or 4 by 5 in. is better than that on the commonly used 4-by-36-mm photographic film.

includes fluoroscopy, good roentgenograms in various directions and with various exposures, Bucky films and so forth. One danger of the method lies in the possibility that doctors and patients may not appreciate its limitations, thereby creating an unjustified feeling of safety. For example, if a patient has recently had a negative examination by screen photography, a more adequate roentgenological examination may be delayed if he should develop clinical symptoms. It is likely that the technical qualities of the screen photographs will improve in the near future, so that their clinical use may become advisable in many cases. The danger which is inherent in any serial examination will remain unless the incompleteness of such an examination is adequately stressed.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Annual Meeting, May 21, 1940

THE annual meeting of the Council of the Massachusetts Medical Society was held in the Swiss Room of the Copley-Plaza Hotel, Boston, on Tuesday, May 21, at 10.30 a m. The president, Dr Walter G Phippen, Essex South, was in the chair, and 261 councilors were present (Appendix No 1).

The records of the meeting of February 7, 1940, published in the *New England Journal of Medicine*, issue of March 7, 1940, were presented by the Secretary and approved by the Council.

The roll call of the nominating councilors by the Secretary was as follows: W D Kinney, Barnstable, W H Allen, Bristol North, E F Cody, Bristol South, F W Snow, Essex North, Horace Poirier, Essex South, F J Barnard, Franklin, G L Schadt, Hampden, L N Durgin, Hampshire, R R Stratton, Middlesex East, F L Gage, Middlesex North, A W Dudley, Middlesex South, D D Scannell, Norfolk, W G Cur-

tis, Norfolk South, W H Pulsifer, Plymouth, R L DeNormandie (alternate), Suffolk, R P Watkins, Worcester, and C B Gay, Worcester North. (There was no representative from the Berkshire district.) The nominating councilors retired to Parlor A for deliberation.

REPORTS OF STANDING COMMITTEES

Membership

The chairman, Dr H Quimby Gallupe, Middlesex South, read for the purpose of record the supplementary report of his committee which was omitted at the February meeting but published as a supplementary report in the *New England Journal of Medicine*, issue of March 7, 1940, in connection with the February meeting. This part of the report was accepted and the recommendations adopted by the Council.

Dr Gallupe then proceeded with the reading of the current report (Appendix No 2). The

committee recommended that eight fellows be allowed to retire, five be allowed to resign, three be allowed to have their dues remitted, nine be allowed to change their districts without change of legal residence, and two be recommended for affiliate fellowship in the American Medical Association. The report was accepted and the recommendations adopted.

Ethics and Discipline

The report (Appendix No 3) was presented by the chairman, Dr Robert L DeNormandie, Suffolk.

In response to a question by Dr Norman A Welch, Norfolk, the President stated that the formal complaint made in February concerning certain fellows of the Society was still in committee. The report was accepted by vote of the Council.

Medical Education and Medical Diplomas

The report (Appendix No 4) was presented by the chairman, Dr Reginald Fitz, Suffolk, and was duly accepted.

Dr Fitz then introduced a recommendation from the committee that the Committee on Medical Education and Medical Diplomas be directed to redraft Section 5 of Chapter VII of the by laws and to report at the next meeting of the Council.

The Secretary suggested that the recommendation be somewhat more inclusive and include the phrase "and such other by laws as may apply." The suggestion was accepted by Dr Fitz. The altered recommendation was duly passed by the Council.

State and National Legislation

The report was presented by the chairman, Dr E. Lester Merritt, Bristol South. This being an off season, with regard to state legislation, there were no local matters to report. The committee met on May 15 to discuss certain bills now before Congress. The committee recommended that House Bill 8963, introduced by Representative Toland of California, be opposed. This bill would give to chiropractors the right to treat injured federal employees who are entitled to benefits under the United States Employees Conference Act. The hearing was scheduled for May 22. The Council voted to approve of a telegraphic protest to the Judiciary Subcommittee in the name of the Society. The report was accepted.

Medical Defense

The chairman, Dr Arthur W Allen, Suffolk,

presented the report of the committee (Appendix No 5). The Council voted to accept it.

REPORTS OF SPECIAL COMMITTEES

Postgraduate Instruction

The report (Appendix No 6) was presented by the chairman, Dr Frank R Ober, Suffolk, and was accepted by the Council.

The Council approved of the recommendation that the committee be continued.

Physical Therapy

The report (Appendix No 7) was presented by the chairman Dr Franklin P Lowry, Middlesex South and was duly accepted.

Industrial Health

The report (Appendix No 8) was presented by Dr Louis R Daniels, Middlesex South, and was accepted by vote of the Council.

Public Relations

The report (Appendix No 9) was presented by the secretary of the committee, Dr Elmer S Bagnall, Essex North.

Paragraph 1 of the report was accepted and approved.

Paragraph 2 was accepted and the recommendations approved. Under the by laws, the request for an appropriation of \$150 was referred to the Committee on Financial Planning and Budget.

In connection with Paragraph 3, Dr Thomas H. Lanman, Suffolk, chairman of the special committee appointed by the President to study medical costs insurance plans, was asked to present his report which was made a part of the report of the Committee on Public Relations.

The Committee on Public Relations made the following recommendations:

Any plan for prepaid medical care, sponsored by the Massachusetts Medical Society should meet the following five requirements:

- 1 That it be on a voluntary basis and available to those with low or moderate incomes.
- 2 That it include the subscriber's free choice of physician.
- 3 That the Massachusetts Medical Society have supervisory control through the properly appointed general and local committees.
- 4 That it comply with the laws governing insurance in this state.
- 5 That the education of the public regarding such plans be left insofar as possible to the physician and his individual patient of the individual locality but working with and under a special committee duly appointed by the state society.

This portion of the report was duly accepted. There was some discussion regarding the phrase

"free choice of physician" Dr Lincoln Davis, Suffolk, was of the opinion that the phrase sounded well, but its inclusion would make it difficult to maintain standards of practice. Dr Brainard F Conley, Middlesex South was of the opinion that the recommendation made was important in that it encouraged a continuation of doctor-patient relations. Dr Merritt agreed with Dr Conley. Dr Welch pointed out that legally the only method of qualifying men to practice medicine rests with the Board of Registration in Medicine.

After some further discussion, the Council moved to adopt the recommendations of the Committee on Public Relations. It was then voted to accept the report of the committee as a whole.

Restoration to Fellowship

Restoration to fellowship, with the usual provision regarding payment of dues, was authorized by the Council for the following four former members:

- Lionel M Cole, Pittsfield (Committee Maurice S Eisner, Garvey Adeson and George M Shipton)
- Paul R. Donovan, Revere (Committee Earle M. Chapman, Harold L. Musgrave and George L. Gately)
- H R. Record, Quincy (Committee Cornelius J Lynch, Cornelius A. Sullivan and William J McCausland)
- Frank J Vaccaro, Pittsfield (Committee Henry H. Bard, Newell N. Copeland and Modestino Criscitello)

Restoration to fellowship was not recommended for the following former member:

- Roland O Parris, Falmouth (Committee John I B Vail, John P Nickerson and Julius G Kelley)

Nominating Committee

Dr Edmond F Cody, Bristol South, reported for the Nominating Committee the following nominations for office:

- For president Walter G Phippen, Salem.
- For vice president Frank R. Ober, Boston.
- For secretary Alexander S Begg, West Roxbury.
- For treasurer Charles S Butler, Boston.
- For orator A. Warren Stearns, Billerica.

There being no further nominations, it was voted that nominations cease and that the Secretary be directed to cast one ballot for the officers nominated by the committee. The Secretary announced that he had cast the ballot and that the officers were duly elected.

APPOINTMENTS OF COMMITTEES

The President then proceeded to announce his

nominations for appointment to the various standing and special committees (These committees will be published with the proceedings of the Society in the July 4, 1940 issue of the *Journal*). The list of appointments was duly approved by the Council.

The following committees were approved by the Council to consider the petitions for restoration to fellowship of the following six former members:

- For Julian C Gant, Arlington
Edwin P Suchner, Alfred Weller and Letitia D Adams
- For Edward J Kelley, Watertown
Albert B Toppan, Pericles Canzanelli and Eugene F Gorman.
- For Burton E. Lovesey, Roslindale
Guy F Blood, John F Ford and John J Elliott.
- For Julian D Lucas, Brookline
Edward L. Kichham, Frederick J Bailey and Maurice Gerstein.
- For Joseph Rosenthal, Roxbury
Sidney H. Weiner, Hyman Morrison and Joseph Laserson.
- For Louis F Salerno, East Boston
Harvey A. Kelly, George H. Schwartz and Raymond B Parker.

INCIDENTAL BUSINESS

The application of Dr Thurlow H Pelton, of Pittsfield, was received at headquarters too late to be included in the list of applicants published in the *Journal*. He appeared before the Board of Censors and was duly examined and passed. The Council approved of the action taken.

The Council voted to approve the action of the Board of Censors of Middlesex South District in giving a postponed examination to Dr Alan R. Moritz who did not receive official notification of the regular meeting.

The Council voted to approve the President's appointment of Dr Ernest L. Hunt, Worcester, as alternate delegate to the House of Delegates of the American Medical Association, to take the place of Dr Arthur W. Marsh.

The Secretary called attention to the necessity for the councilors to sign the attendance books. Reports of attendance by councilors are compiled from these books and supplied to the various district societies. The nominating committees of the district societies frequently are influenced, in their choice of councilors, by these reports.

The meeting adjourned at 11.55 a.m.

ALEXANDER S BEGG *Secretary*

APPENDIX NO 2

REPORT OF THE COMMITTEE ON MEMBERSHIP

The committee recommends

1 That the following named eight fellows be allowed to retire under the provisions of Chapter I, Section 5, of the by-laws

Blanchette, William H, Fall River
Doucett, Frederick L, East Weymouth
Leach, Albert C, Orange
Park, Francis E., Stoneham
Patterson, Alice M, Marblehead, with remission of dues for 1940
Pothier, Joseph C, New Bedford, with remission of dues for 1940
Potter, Lester F, New Bedford
Starbird, Edward P, Dorchester, with remission of dues for 1940

2 That the following named five fellows be allowed to resign under the provisions of Chapter I, Section 7, of the by laws

Bushold, Fred G, Hampton, New Hampshire, with remission of dues for 1940
Durant, Richard C, Honolulu, Hawaii
Shain, Joseph H., Boston, with remission of dues for 1938, 1939 and 1940
Teel, Harold M., Polson, Montana, with remission of dues for 1940
Wattles, Merrill, Palatka, Florida

3 That the following named two retired fellows be recommended for affiliate fellowship in the American Medical Association

MacCarthy, Francis H, Gilford, New Hampshire
Starb rd, Edward P, Dorchester

4 That the dues of the following named three fellows be remitted under the provisions of Chapter I, Section 6, of the by-laws

Booth, Ernest L., East Boston, 1937, 1938, 1939 and 1940
Campbell, Franklin E, West Medford, 1940
Strongman, Bessie T, Pittsfield, 1940

5 That the following named nine fellows be allowed to change their membership from one district society to another without change of legal residence, under the provisions of Chapter III, Section 3, of the by-laws

From Middlesex South to Suffolk

Castleman, Benjamin, Belmont

APPENDIX NO 3

REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

The Committee on Ethics and Discipline has held four long meetings since the last report. Besides these meetings of the whole committee, the secretary and the chairman have answered over the telephone many questions of minor importance. Scarcely a week goes by that some fellow does not appeal for clarification of some point that disturbs him. In the large majority of such appeals, one or the other of the committee usually can straighten out the difficulty and the matter does not come before the whole committee.

Petty publicity causes the committee much annoyance. Letters are constantly received from fellows enclosing photographs of physicians which have appeared in newspapers. In two or three cities, so called "personality sketches" of doctors have made their appearance. Cards in various church or fair programs, signs several feet long and illuminated, signs with the doctor's name and his specialty, advertisements in local newspapers giving addresses, office hours, telephone numbers and types of work, as well as statements of membership in societies—these are a few of the types of publicity that the committee has attempted to stop. In all cases the physician's attention has been called to the objections to such publicity, and they have given it up. The nuisance, however, persists, and the committee believes that this statement calling the attention of the fellows to such undignified practices may help to put a complete stop to them.

Several complaints against fellows have been made which have been investigated and satisfactorily adjusted.

The committee has given hearings to three fellows, two because of complaints made by patients regarding fees. These were studied and satisfactory adjustments were made. The third hearing was to a fellow charged with incompetent surgery. The various aspects of this case were discussed with the fellow. He was frankly and severely reprimanded by the committee.

When the Medical and Surgical Associates met with the committee, Dr Phippen presided. The chairman took no part in the presentation of the facts, and was not present during the subsequent discussion by the committee. The committee has the whole problem before it for further consideration.

Several matters are still being investigated on which no final conclusion has been reached.

ROBERT L. DENORMANDIE, *Chairman*

APPENDIX NO 4

REPORT OF THE COMMITTEE ON MEDICAL EDUCATION
AND MEDICAL DIPLOMAS

The committee has met twice during the past year. Our chief duty has been to scrutinize diplomas presented by candidates for fellowship who are graduates from foreign medical schools or from schools not recognized by the Society. At our two meetings we have interviewed 104 such candidates. Of such candidates whose diplomas were recognized by the committee, 42 have been passed by the examining censors in the various districts. Thus, of the 245 names added to the roster of the Massachusetts Medical Society since the last annual meeting 17 per cent are those of graduates of foreign or unrecognized schools.

The problem of the graduate of a foreign medical school or of an unrecognized school continues to be no less baffling now than in previous years. The ordinary doctor licensed to practice medicine in Massachusetts finds that membership in the Massachusetts Medical Society is useful. Membership is particularly useful as a means of opening the door to hospital appointments. It is a rare hospital which will accept on its staff a physician who has not among his credentials his certificate of membership.

On the other hand, medical educators are of the opinion that internships now are an integral part of a doctor's educational program. At the October meeting of the Association of American Medical Colleges, this organization voted that its executive council be authorized to proceed with the formulation of minimum educational standards for acceptable internships and prepare a list of hospitals meeting these standards. Many Massachusetts hospitals meet these standards. Many Massachusetts hospitals wish to train interns and appreciate that unless their staff is sufficiently competent recognition for intern training is unlikely. Thus, your committee finds itself balanced on a precarious perch. On the one hand we are assailed by fellows who believe that our interpretation of the by laws is too liberal, and on the other by doctors who say earnestly that the by laws, as we have interpreted them, discriminate unfairly against certain licensed practitioners who have every right, under the laws of the Commonwealth, to work without stigma.

Your Committee finds the present by laws, as they concern our work, not entirely satisfactory. As the number of applicants who appear before us has increased year by year we have come to serve more as a committee on credentials than for any other purpose and we believe that the several districts might set up credential committees which could operate locally with greater intelligence than can we. Such subcommittees should be in a better position to obtain truly confidential information concerning candidates than are we and should be of great assistance to us in helping to select the best candidates for membership in the Society from doctors who are graduates of foreign medical schools or of schools not recognized by the Society. Therefore your committee asks for a resolution directing it to re-draft Section 5 of Chapter VII of the by laws and to report on this matter at the next meeting of the Council.

This year a prize of fifty dollars was again offered for the best written and most comprehensive case report submitted by an intern holding an internship in any Massachusetts hospital approved by the American Medical Association for intern training. This is a valuable means of stimulating better writing and clearer thinking among younger men. The president of the Boston Medical Library, the editor of the *New England Journal of Medicine* and the chairman of the Committee on Medical Education

and Medical Diplomas served as judges. Six case reports were submitted. The prize was awarded to Dr. Victor G. Balboni, a graduate of the Harvard Medical School in 1939 for his case report "Multiple Pulmonary Thrombi Associated with Cyanosis and Right-sided Cardiac Hypertrophy." This case was studied by him while he was an intern in pathology at the Peter Bent Brigham Hospital.

Your committee has followed the postgraduate education program of the Society with much interest. The courses given in the districts and the New England Postgraduate Assembly appeal to us as being efforts in the right direction. This year's program of the annual meeting also appears to us to be of greater educational value than ever before.

REGINALD FITZ, *Chairman*
ARCHIBALD R. GARDNER
GEORGE D. HENDERSON
JOHN P. MONKS,
A. WARREN STEARNS.

APPENDIX NO 5

REPORT OF THE COMMITTEE ON MEDICAL DEFENSE

During the past year there have been two new cases accepted for defense. In each there is no evidence of malpractice. Both cases will be allowed to come to trial.

Two cases have been disposed of during the past year. One, which came to trial, had a verdict returned by the jury for the defendant. The other case reached trial but a companion case defended by an insurance company was settled by the company in such a way that the member who was being defended by us was also released as a part of the settlement.

There are at present a total of eight cases pending. There is one threatened lawsuit which probably will not be carried any farther.

The committee believes that the Society should continue to maintain this legal protection against malpractice suits even though a good percentage of the members carry malpractice insurance. The mere fact that the Society will not settle any suit out of court has a definite reaction against the establishment of such suits; thus, we believe, to be beneficial to the Society as a whole.

ARTHUR W. ALLEN, *Chairman*
HORATIO ROGERS, *Secretary*
EDWIN D. GARDNER,
FREDERICK B. SWEET
WILLIAM R. MORRISON

APPENDIX NO 6

REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

On April 25, 1940, the postgraduate extension courses ended for the academic year 1939-1940. The total enrollment for this year was 984, a gain of 23.7 per cent over the previous year, the enrollment in 1938-1939 being 795. The detailed attendance record is attached. The Society again presented the extension programs in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau. The Department of Public Health has assisted the committee in carrying forward this program of instruction; the committee wishes to thank Dr. Jakiniah, the commissioner of public health for his co-operation.

Teaching clinics were instituted in Franklin, Berkshire and Bristol counties, these were rated very successful and show that case demonstration and teaching can be done well in any locality where the profession will provide the necessary facilities. The committee hopes that other districts will try this method of teaching.

Clinical teaching was given again this year in gonorrhea and syphilis, at the Boston Dispensary Gonorrhea Clinic, student physicians made forty-nine clinic visits, while at the Massachusetts General Hospital Syphilis Clinic,

ATTENDANCE — POSTGRADUATE EXTENSION COURSES

| DISTRICT | PLACE | 1938 | 1939 | 1940 |
|-----------------|-------------|-------------|-------------|------|
| Barnstable | Hyannis | 22 | 33 | 23 |
| Berkshire | Pittsfield | 55 | 45 | 50 |
| Bristol North | Taunton | 27 | 31 | 20 |
| Bristol South | Fall River | 20 | 36 | 22 |
| | New Bedford | 38 | 34 | 34 |
| Essex North | Lawrence | 31 | 48 | 52 |
| Essex South | Salem | 58 | 54 | 59 |
| Franklin | Greenfield | 28 | 27 | 47 |

| Worcester | Milford | 23 | 20 | 30 |
| | Worcester | (no course) | (no course) | 45 |
| Worcester North | Fitchburg | 46 | 35 | 26 |
| Totals | | 708 | 795 | 984 |

student physicians made one hundred and eleven clinic visits. The attendance has dropped from last year but the committee hopes to improve this important phase of postgraduate instruction.

The outline for next year's postgraduate extension program has been made out and a budget presented to the Department of Public Health which will submit it to the government agencies in Washington. It is highly probable that this successful co-operative plan will be continued.

The New England Postgraduate Assembly has been organized for next fall. The assembly will be held in Sanders Theatre and Memorial Hall on Wednesday and Thursday, November 13 and 14, 1940. The speakers will be as follows:

- Dr. Fred L. Adair, Chicago (obstetrics and gynecology)
- Dr. Henry W. Cave, New York City (gastrointestinal diseases)
- Dr. Russell L. Haden, Cleveland (blood diseases)
- Dr. Sumner L. Koch, Chicago (trauma and infection)
- Dr. Robert F. Loeb, New York City (diabetes)
- Dr. T. Grier Miller, Philadelphia (gastroenterology)
- Dr. Oliver S. Ormsby, Chicago (dermatology)
- Dr. Percy S. Pelouze, Philadelphia (urology)
- Dr. Tracy J. Putnam, New York City (neurology)
- Dr. Ralph M. Waters, Madison, Wisconsin (anesthesiology)

The detailed program will be printed in the *New England Journal of Medicine* and also mailed to every physician in the sponsoring states next September.

The committee wishes to express to the faculty of the

extension courses and teaching clinics the appreciation of the Society for its services in maintaining the high standard of teaching.

The fourth annual meeting of the Associated State Postgraduate Committee will be held on June 12, 1940, in New York City during the meeting of the American Medical Association. The committee recommends that the Society authorize the executive committee to send delegates to this meeting.

The committee wishes to express sympathy to the Medical Society of the State of New York in the death of Dr. Thomas P. Farmer, of Syracuse, who was chairman of its postgraduate committee for many years. He was a pioneer in many phases of postgraduate medical education. Dr. Farmer was vice-chairman of the Associated State Postgraduate Committees and was a champion of progressive educational ideas. He succumbed to the effects of radium used in his professional work over a period of many years.

It is recommended that the committee be continued.

FRANK R. OBER, *Chairman*,
LEROY E. PARKINS, *Secretary*

APPENDIX NO 7

REPORT OF THE COMMITTEE ON PHYSICAL THERAPY

During the past year there has been a decidedly increased interest in more adequate undergraduate instruction in physical therapy by medical schools throughout the country. Certain physical therapy methods and principles are now recognized by the medical profession generally as a definite aid in the treatment of various pathologic conditions.

Your committee has for several years attempted to encourage the inclusion of this subject in the curriculums of all the medical schools in this region. The University of Vermont College of Medicine has had definite instruction in this field for four years. Tufts College Medical School began with two hours' instruction a few years ago, and offered eight hours' instruction this year.

A department of physical therapy has recently been started at the Massachusetts General Hospital, and we hope that it will attain the results already achieved by other hospitals of its size and influence in other parts of this country.

This is a helpful sign for future physicians. For those already in practice who wish a practical summary of this subject a cinema has been prepared which demonstrates various methods used in physical therapy. The cinema and speakers may be obtained for medical meetings by communicating with the committee.

FRANKLIN P. LOWRY, *Chairman*
GEORGE R. MINOT,
ROBERT B. OSGOOD

APPENDIX NO 8

REPORT OF THE COMMITTEE ON INDUSTRIAL HEALTH

This committee was first appointed on April 27, 1939, and reappointed June 13, 1939, to co-operate with the American Medical Association in its program for the advancement of better medical care.

Our field is particularly industrial and we are concentrating on the type of activity which we believe will be

helpful to the doctor who is partly or wholly occupied with industrial problems.

The members of the committee are all connected with industry and also maintain contacts with those organizations best equipped to be of help in carrying out this program. These contacts are as follows:

- The Conference Board of Physicians in Industry (National Industrial Conference Board)
- The National Association of Manufacturers
- The Air Hygiene Foundation of America
- The Harvard School of Public Health (Division of Industrial Hygiene)
- The Massachusetts Department of Labor and Industries (Division of Industrial Hygiene)
- Several insurance companies which provide workman's compensation insurance
- A number of individuals especially equipped to advise on industrial medical problems

The committee was represented by two of its members at the second annual Congress on Industrial Health of the American Medical Association at Chicago, January 15 and 16, 1940.

In order to bring the committee to the attention of those whom we are trying to interest it is our opinion that publication of the committee reports in the *Journal* will help.

Three reports have been so published, and we propose to continue along this line until a more intensive program is determined upon.

Four meetings have been held during the year which have been productive in the way of ideas leading toward this more intensive program.

Requests for advice and assistance have been received and we are trying to render service in all these cases.

APPENDIX NO 9

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

1. The Committee on Public Relations considered with a representative of the Massachusetts Department of Public Health and Dr. T. Duckett Jones a proposed plan for the inclusion of a program in this state for the care of initial attacks and the follow-up of children under twelve years of age with rheumatic heart disease. Action on this was postponed pending opportunity for its consideration by the district societies.

2. The committee believes that it is highly desirable that a special study be conducted looking toward better understanding between the profession and the authorized agencies involved in the administration of tax-supported medical care in Massachusetts and urges the adoption of the following recommendation:

That the Council authorize the President to appoint a special committee, sufficiently large to be representative of the State to make a study of tax-supported medical care in Massachusetts, enlisting the co-operation of state, city and town welfare, old age and veterans relief administrators and looking toward better standards of care and better mutual understanding of problems of the physicians and of the public agencies.

That the Council appropriate \$150 for the expenses incident to this study.

And that this special committee report to the Council through the Committee on Public Relations.

3. The Committee on Public Relations submits and endorses the report of the special committee appointed by the President at the last meeting of the Council for the study of medical-costs insurance plans. [Dr. Lanman, chairman of this special committee, then read his report.]

This committee has studied carefully the problem of how the Massachusetts Medical Society can best carry out the vote of the Council of April 1939 to wit:

Voted that the Massachusetts Medical Society take the initiative in the formation of a corporation, non-profit in character which shall seek to pay the medical-care costs of patients." The present duty of this committee is primarily to build a solid foundation on which the detailed structure of such a plan can rest. The foundation must be such that it will merit and receive the wholehearted co-operation of the members of the Society. This committee cannot, and we believe should not attempt at this time to present complete and detailed plans. It should leave the way open for changes and modifications in the detailed applications of this plan that may appear desirable and for which experience may show the need. It is obvious that the problems of various individual localities are different. No one plan can cover effectively the divergent needs of the rural community of the State, the small industrial community and the metropolitan center. Any such plan to be effective will require a great deal of further time and effort. The present plan recently put in effect in the State of Michigan is the result of ten years of careful study and the expenditure of over \$30,000 of the society's funds. For the development of these details, however we have the advantage of the study of the plans of other states, notably those of Michigan and New Jersey. The plans for the superstructure must be flexible. The foundation must be firm and secure. The committee takes cognizance of the fact that the Society has already instructed this committee to proceed with drafting and submitting to the Legislature a proper enabling act which if passed will permit such a plan to operate.

This report discusses five fundamental points which are the basis for the five recommendations we offer namely:

1. Any plan for prepaid medical care or service sponsored by the Massachusetts Medical Society should be on a voluntary basis and should be available to those with low or moderate incomes. The committee is not at this time prepared to express exactly just what limits should be applied in defining low or moderate incomes. The committee at this time asks only that this principle be accepted in abstract.

2. Any plan for prepaid medical care or service should include the subscriber's free choice of physician. This is defined as the choice ordinarily exercised by a patient in the selection of his family physician.

3. The Massachusetts Medical Society should have a supervisory control over any such plan by properly appointed committees, both general and local. The Massachusetts Medical Society under its present charter cannot as a society be made a part of the structure of a plan for prepaid medical care.

4 Any such plan for prepaid medical care or service should comply with the laws governing insurance in this state. For this, four conditions must be met

- a An enabling act of the Legislature
- b Adequate public control by lay and professional groups, the professional groups to be chosen by the Society
- c A non profit basis of operation
- d Exemption of taxes, both federal and state

Nothing in the above conditions, however, is to be construed as being in conflict with the service ofered by any insurance company legally chartered to do business in Massachusetts

It is pertinent to point out that the present plan of the Medical Society of New Jersey was at first not incorporated under the State Commissioner of Banking and Insurance. In spite of legal opinion that such a plan was not insurance, it seemed wiser not only as regards the state society but also as regards protection to the subscriber that its plan be incorporated so as to meet the requirements of the state insurance laws

5 Any plan for prepaid medical care or service for the income groups under consideration involves the education of the public regarding its benefits. This is properly the duty of the family physician, and also requires the creation of a special committee to deal with the public, particularly as regards solicitation of subscribers

Only these five principles are presented at this time. Further details, particularly those relating to plans for the enabling act of the Legislature will, of course, be presented to the Council for its approval as this study progresses

We believe the adoption of these five general and broad principles will serve to establish a foundation for a plan that will operate justly, wisely and in the best interests of the profession and the public

THOMAS H. LANMAN, *Chairman*

The Committee on Public Relations recommends to the Council the adoption of the following principles

We recommend that any plan for prepaid medical care sponsored by the Massachusetts Medical Society should meet these five requirements

- 1 That it be on a voluntary basis and available to those with low or moderate incomes.
- 2 That it include the subscriber's free choice of physician
- 3 That the Massachusetts Medical Society have supervisory control through the properly appointed general and local committees
- 4 That it comply with the laws governing insurance in this State
- 5 That the education of the public regarding such plan be left, insofar as possible, to the physician and his individual patient of the individual locality, but working with and under a special committee duly appointed by the Society

The attention of the Council is invited to the fact that this special committee has already been instructed to endeavor to carry out the vote of the Council of April, 1939, namely, that the Massachusetts Medical Society take the initiative in the formation of a corporation, non profit in character, which shall seek the procurement of enabling legislation at the next session of the Legislature.

The attention of the Council is invited to the fact that the Medical Society of the District of Columbia after thorough investigation has postponed indefinitely the operation of its tentative plan for medical-costs insurance, because of insufficient demand by the people at this time for this kind of service

The Council will also be interested in the fact that the State of Connecticut and some other states have procured enabling legislation but have not yet initiated the service. It will be recognized that careful study and observation of existing and proposed similar plans will be necessary before we can undertake anything in this field, and that the Council will be informed and asked to endorse the enabling legislation and any proposed plans before they are submitted to the Legislature or to the people.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26251

PRESENTATION OF CASE

A twenty-one year-old soda fountain clerk was admitted to the hospital complaining of lower abdominal cramps of five days duration.

The history was obtained chiefly from the patient's parents as he was too ill to give a coherent account.

The patient had been well until one year before admission when he had a night long attack of severe, cramp-like, lower abdominal pain without diarrhea which cleared within some twenty-four hours and required no medical attention. The patient had appeared to be pale and tired for one month before admission. This was attributed to late working hours and poor eating habits. He seemed otherwise well until five nights before entry when, at 3:00 a.m., he suddenly experienced severe, cramp-like, lower abdominal pain. The type of pain was said to have reminded the patient's mother of the illness of another of her sons who had had a ruptured appendix. The cramps persisted intermittently through the night. They were diffuse and low in the abdomen without definite localization. A physician was called that morning and he stated that the illness was not acute appendicitis. The temperature was 100.2°F. A soap-suds enema was given with good results and the passage of much flatus. The pains, however, continued, he became nauseated and vomited immediately afterward. The cramps increased in severity during the remainder of the day, but nevertheless he managed to sleep well. Four days before admission his temperature was 99°F. His food intake was limited to fluids. In the afternoon of this day the pain and temperature elevation returned. At 6 p.m. he experienced his first shaking chill which lasted some fifteen minutes. He was slightly disoriented, and the temperature rose to 103°F. His physician referred him to an outside hospital where during the next three days, the patient had three more shaking chills associated with mild delirium. The last episode occurred twelve hours before admission to this hospital. Throughout this interval the bowel movements were loose, but there was no real diar-

rrhea. The pain became steadier, and there seemed to be a questionable localization of its point of maximum intensity in the right lower quadrant of the abdomen. He was seen in consultation by another physician who referred him to this hospital for further diagnostic studies. There had been almost complete anorexia throughout the entire illness. There had been no known exposure to a contaminated water or milk supply. He was an extra hand in a large drugstore and took many meals there. None of his relatives or friends had experienced a similar illness.

The remaining family and past histories were non-contributory.

Physical examination revealed a remarkably pale, sick looking, thin, flat-chested man who complained of severe abdominal pain. He had a doughy, slightly distended, slightly tympanitic, tender abdomen, with maximal tenderness to deep palpation located in the right lower quadrant. Rebound tenderness was referred to the same region. No costovertebral tenderness was elicited. The liver and spleen were not felt. Peristaltic sounds were high-pitched and active. On fixing the iliopectineal muscles, motions of the legs caused greater pain in the right abdomen than in the left. The rectal examination was negative, and the heart, lungs and extremities were normal.

The temperature was 105°F (a few minutes after a chill), the pulse 90, and the respirations 20.

Examination of the blood revealed a red-cell count of 4,800,000 with 88 per cent hemoglobin, and a white-cell count of 9700 with 82 per cent polymorphonuclears. The urine was negative. The corrected sedimentation rate of the blood was 0.8 mm per minute. The hematocrit was 41 per cent. A blood culture showed no growth. The serum van den Bergh was 1.0 to 1.5 mg per 100 cc with a biphasic reaction.

The patient developed tenderness over the liver edge and the organ slowly enlarged. He continued to run a high spiking temperature with frequent chills. Jaundice appeared and gradually increased. He was given intravenous sulfapyridine to a blood level of 6.2 mg per 100 cc, but because of the obvious gravity of his illness and the steadily increasing symptoms, he was operated on during the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. GREENE FITZHUGH: It seems to me that this was probably a surgical condition. I wonder why he was not operated on before. He could not

have had so much in the way of physical signs in the other hospital as he had here

In summary, there is a five-day story before he came to this hospital of cramp-like lower abdominal pain. A year previously he had had a similar attack which lasted twenty-four hours. On the second day of his illness he had a shaking chill with a temperature of 103°F. On the fourth day he was sent to an outside hospital where he had a daily chill and the pain became localized in the right lower quadrant. I should say it was an excellent story for acute appendicitis followed by pylephlebitis. I assume the diagnosis could not be made early because it was a retrocecal appendix, and no spasm or tenderness was felt over the abdomen until the illness had progressed for several days. The most important finding against my diagnosis is the white-cell count of 9700—usually there is quite a high count with pylephlebitis. I believe that all the other conditions that ought to be considered are likewise surgical. I do not know of any medical condition that gives this picture. Did this case end in death or did it not?

DR TRACY B MALLORY We have chosen to stop the history at the operation.

DR FITZHUGH I assume that it did. Of course if it did not end in death that would almost rule out the diagnosis of pylephlebitis. Assuming it did not end in death, catarrhal jaundice should be considered and might give a white-cell count like this, however, I never saw a case with as many shaking chills as this one had. The liver in catarrhal jaundice usually does not enlarge with such rapidity as it did in this case.

Should we consider regional ileitis? A very rare case starts out, as one of acute appendicitis does, with symptoms of right lower-quadrant pain. That would be so rare that I should not like to give it any serious consideration. A gastrointestinal series would help with the diagnosis. A cecal diverticulum ought to give symptoms of intestinal obstruction with a good deal more vomiting. He had. Should we consider intussusception, that also leads to more vomiting, and expect several small bloody movements, and not have. He probably also would have more severe pain.

Should we consider gallstones? One can have them at twenty-one, but it is an unlikely diagnosis. Furthermore, it is very rare to have pylephlebitis after cholecystitis. The story was one of lower abdominal pain, which ought to put the lesion in the region of the appendix or the cecum, with pain referred below the umbilicus. It would not be a lesion of the large intestine. I assume he had pancreatitis because in such

cases the pain is usually localized in the epigastrium, radiates through to the back, and is steady and excruciating, with more vomiting and shock than he had. About half the cases of pylephlebitis follow appendicitis. A rare case follows gastric or duodenal ulcer, and a few are secondary to ischio-rectal abscess, pancreatitis, cholecystitis and abscess of the spleen. I do not believe they are worth considering seriously.

This young man was not operated on for several days because his physical signs and laboratory findings were obscure. They fit in best with a diagnosis of acute appendicitis followed by pylephlebitis, in spite of the low white-cell count.

DR. MALLORY Do any surgeons care to comment, or other medical men?

DR MILTON H CLIFFORD After the Chicago amebic dysentery epidemic were there not a number of liver abscesses not dissimilar to this case?

DR WYMAN RICHARDSON I remember one that was similar to this case, however, I should hate to make that diagnosis here. I agree with Dr Fitzhugh.

DR LELAND S MCKITTRICK Dr Fitzhugh has made this so easy that it is rather embarrassing to some of us surgeons. It must be particularly embarrassing to a most highly respected member of our surgical staff who sent the patient in as a typhoid case because of the fever, low pulse and low white-cell count, and one wonders if the problem was as difficult as we made it out. He entered the Emergency Ward and went on the medical service, so apparently the diagnosis was not obvious to the members of the hospital staff who saw him on admission. The diagnosis given by Dr Fitzhugh is the diagnosis which was made after his admission to the hospital, and I think he has gone right to the point very clearly and very well. I should like to bring out one point in relation to early diagnosis. I saw him the morning after his admission, and I defy anyone to have made an accurate diagnosis of appendicitis on the physical findings which he presented that morning. Save for abdominal distention, his physical findings were as nearly zero, so far as the abdominal and rectal examinations were concerned, as is possible. I bring that out because I think it is of utmost importance to be as decisive and conclusive as Dr Fitzhugh has been on slight evidence, and that evidence, I think, is covered by him when he said, "I do not know of any medical condition that gives this picture." The early diagnosis and early treatment of this group of cases must be based on the history of the chills and fever, a little abdominal pain and most in

definite findings in the absence of any other explanation

Would you like me to go farther and say what we found?

DR. MALLORY If you had seen this patient within the first twenty four hours of the illness, do you think you would have operated at that time?

DR. McKITTRICK I think I should have, simply because I had seen one similar case before. An early operation would have made a great deal of difference.

There have been reported in the past year three or four cases of apparent pylephlebitis which have been cured by chemotherapy.* I put that in because Dr. Fitzhugh was going to base so much of his diagnosis on fatal termination, and also in partial justification of the treatment that was carried out on this young man after the diagnosis had been made. I think that is of importance because there has been a great deal written about the value of ligation of the ileocolic vein in the early stages of pylephlebitis. There are reported cases in which this procedure seems to have given dramatic results. It was advocated for this patient.

DR. MALLORY Do you want to describe the operative findings?

DR. McKITTRICK We operated and found a thrombosed cord along the course of what we interpreted as being the ileocolic vein. It is of significance that when that was done, approximately nine days after onset, this cord, which was at least 5 mm. in diameter, was nonpulsating and we could not identify the artery. There were marked edema of the mesentery and enlargement of the lymph nodes, both of which obscured the anatomic landmarks. We could feel only this inflammatory cord running along the course of the vessels and were unwilling to ligate it without identifying the artery. We were unable to feel pulsation. We finally identified it as the artery by opening it but did not have the courage to ligate both artery and attached vein. We stopped the operation at that point after taking out the appendix. The appendix was gangrenous.

There is one other point of importance. When we first opened the abdomen we were doubtful of the diagnosis. There was no excess of free fluid. The omentum was normal to superficial inspection. The appendix was over the brim of the pelvis, the tip gangrenous, with about a table spoonful of pus about it.

CLINICAL DIAGNOSES

Acute appendicitis with rupture and abscess formation
Pylephlebitis
Liver abscesses

DR. FITZHUGH'S DIAGNOSES

Acute appendicitis.
Pylephlebitis

ANATOMICAL DIAGNOSES

(Acute appendicitis)
Phlebitis, right colic and ileocolic veins.
Periphebitic retroperitoneal abscess
Liver abscesses, multiple
Icterus
Pulmonary edema
Operative wound appendectomy

PATHOLOGICAL DISCUSSION

DR. MALLORY Following operation nothing dramatic occurred, although the course was steadily downward. An attempt was made to visualize the expected abscesses in the liver by the use of Thorotrast. Dr. Holmes has the films here.

DR. GEORGE W. HOLMES You can readily see the whole outline of the liver. There are mottled areas of diminished density surrounded by zones of increased density in the liver. Thorotrast is supposed to increase the density in the normal portions of the liver, and if there is an abscess it leaves a dark area on the films, the same thing happening if there are metastatic nodules in the liver. If this does represent abscess formation it would have to be multiple small abscesses. I do not believe this is the normal appearance of the liver following Thorotrast. I should like to add that Thorotrast is a radio-active substance and should never be given except in very doubtful cases or in cases, such as those of advanced cancer in which life-expectancy is reasonably short.

DR. McKITTRICK That was duly considered here and the material was given with the remote hope that it might show a single abscess rather than multiple ones.

DR. MALLORY Do you want to describe the terminal course?

DR. McKITTRICK He simply became more and more jaundiced and gradually went downhill and died—a picture of sepsis and liver damage.

DR. EUGENE R. SULLIVAN I might point out in defense of the medical service that Dr. Beckman and I saw this patient in the Emergency Ward and thought he had a ruptured appendix. We treated

him with Ochsnerization from the moment he came into the hospital

DR MALLORY The postmortem examination showed that he did have pyelphlebitis and extensive abscess formation in the liver. The abscesses were so numerous and small and so widespread that drainage would have been quite out of the question. The path of the infection was somewhat peculiar. The ileocolic and right colic veins were locally thrombosed, but the thrombosis did not extend to the portal vein. On the other hand, a retroperitoneal abscess was found at approximately what must have been the bed of the appendix, and this had burrowed its way through the leaves of the mesentery up along all the veins. The veins were quite patent but were bathed in collections of pus which extended all the way up along the portal vein to the hilus of the liver. The major evidence of infection at autopsy was outside the veins rather than in them. There was rather marked dilation of the small bowel, and a kink about an adhesive band was demonstrated in the lower ileum, although it was thought that the adhesions were recent and had probably formed since the appendectomy. The liver abscesses contained gas and foul-smelling pus. The lungs showed marked terminal pulmonary edema and nothing else of great significance.

DR McKITTRICK I find it difficult to clear my mind on this question of ligating the ileocolic vein. It has very free anastomoses, and the blood from that area goes back into the portal system, regardless of whether it goes through the ileocolic vein or takes another channel. Therefore, I wonder how important ligation is, and how much benefit actually comes from closing one main avenue of return which is already thrombosed. Have you any thought on that?

DR MALLORY I do not see any clear logic behind it.

A PHYSICIAN In considering the differential diagnosis at the time of admission was not the initial chill weighty evidence against typhoid fever?

DR RICHARDSON We had one case of typhoid fever in which the patient had a chill. I think repeated chills would be distinct evidence against it.

DR CHESTER M. JONES We have had one or two cases with a single chill. It is very uncommon to have more than one, and that usually comes at the onset, I think.

CASE 26252

PRESENTATION OF CASE

A nineteen-year-old, American born, married Jewish girl was admitted to the hospital complaining of a gradually enlarging abdomen.

Approximately two and a half years before admission the patient first noted the presence of a steady, dull, somewhat ill-defined aching pain located in the left upper abdomen beneath the rib margins. This discomfort continued, and two years before entry she noticed a lump in the left upper abdomen in the same vicinity in which the pain was arising. She was otherwise well and led a fairly normal life until six months before admission, when she became cognizant that the same quadrant of the abdomen was swelling. It seemed to enlarge to the left and was definitely hard. With the increasing abdominal enlargement the patient experienced mild distress in breathing deeply and complained of a sensation of fullness after the ingestion of moderate sized meals. The constant pain had many superimposed sharp twinges. There was no vomiting, but for several months there was slight morning nausea. She denied pregnancy and stated that her catamenia had been normal. The last menstrual period had occurred five days before admission, and the one previous to that occurred three and a half weeks before admission, with normal flow and no clots or pain. During her illness there had been no change in weight. She noted an increasing easy fatigability, and because of the abdominal mass, discomfort while walking.

The family, marital and past histories were non-contributory.

Physical examination revealed a healthy appearing, obese girl. She had a very slight mustache, with stiff but sparse hairs on the chin, hairs on the chest, and a masculine distribution of the pubic hair. Examination of the heart and lungs was negative. The blood pressure was 130 systolic, 100 diastolic. The abdomen was protuberant and slightly asymmetrical, so that the left upper quadrant bulged slightly more than did the right. To palpation, a cystic, smooth ovoid tumor mass was noted, which transmitted a good fluid wave. There was no shifting dullness in the flanks. The tumor moved slightly on respiration. Rectal examination showed a slightly enlarged nulliparous cervix. One examiner averred that the mass seemed to arise from the pelvis, but

stated that there was too much tension for the proper examination of the pelvic organs.

The temperature, pulse and respirations were normal

Examination of the blood showed a red-cell count of 3,700,000 with 75 per cent hemoglobin, and a white-cell count of 12,600 with 75 per cent polymorphonuclears, the smear was essentially normal. The stools were negative for occult blood. A blood Hinton test was negative. The serum nonprotein nitrogen and serum protein were normal. A sugar tolerance test showed the following findings: fasting, 74 mg per 100 cc.; thirty minutes, 176 mg; one hour, 167 mg; two hours 77 mg. Urine examinations showed specific gravities of 1.018 to 1.028, 0 to ++ albumin and 5 to 10 white blood cells per high-power field. A urine culture showed a moderate growth of non-hemolytic streptococci. The vital capacity was 3250 cc.

Röntgenograms of the abdomen revealed an unusually large soft-tissue mass completely filling the upper abdomen and extending downward to the level of the lower border of the left sacroiliac joint. The margins of this mass were smoothly rounded and sharply defined. Intravenous pyelograms showed that the dye appeared promptly on the right side and that the right pelvis and calyces were normal. On the left in one of the films there was a small quantity of dye visualized in a region that probably represented the pelvis of a normal left kidney. Retrograde pyelograms showed normal-sized kidney pelves. The calyces were incompletely demonstrated. The left kidney was displaced downward. All the visible bones appeared definitely older than those indicated by the patient's age. This was particularly true in regard to the lower lumbar vertebrae which showed wavy configurations of their surfaces. All the visible epiphyses were closed. A chest plate revealed high diaphragms, which were regular in outline. The lung fields were clear. The heart was normal in size and shape. There was no evidence of metastases. By fluoroscopy the left diaphragm was seen to move poorly while the right diaphragm showed fair motion. A swallow of barium with fluoroscopic observations showed that the stomach and small intestines were markedly displaced to the right and posteriorly by the huge mass. A barium enema revealed that the splenic flexure was markedly displaced downward by the tumor mass, the transverse colon running along the lower edge of the tumor. The hepatic flexure was not displaced.

The patient was studied extensively. Except for the presence of the abdominal mass she was

asymptomatic. A 17-ketosteroid determination was normal (9 mg per 100 cc.) An operation was performed on the fourteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. ALFRED KRANES The problem here is to guess the localization and nature of this large abdominal tumor. The history is helpful in some respects but is non-contributory, for the most part, since the symptoms are essentially those of pressure from an enlarging abdominal mass, most of her discomfort being due either to pressure on the surrounding organs or to the effects of gravity on the tumor. The history may be of importance in helping us to localize this tumor since the early symptoms were confined to the left upper quadrant and it is fair to assume that the tumor originated in that locality. It probably was present for a good deal longer than two years because by the time patients notice abdominal lumps they usually are quite large and fairly well advanced probably having been present for a long time.

Physical examination is helpful chiefly because it tells us that this mass was apparently cystic, an observation which I think we shall have to take quite seriously. Furthermore a fluid wave was felt which if correct—and I think we have to assume that it was,—confirms the cystic nature of the mass and obligingly allows us to leave out of consideration all the solid tumors of the abdomen thus confining ourselves to the cystic ones. On the law of chances alone it is likely to be cystic because of its size. We have to assume that this was a fairly large mass because of the x-ray description and on account of the history although there is nothing actually said about its size on physical examination. It apparently fills the left side of the abdomen but the physical examination says nothing about that. As to the pelvic examination I do not believe one can tell once a tumor reaches this size, where it originated. The statement that it seemed to arise from the pelvis one cannot take too seriously. On physical examination a tumor of this size may seem to arise anywhere in the abdomen. Apparently it must have been felt by pelvic examination although no statement is made to that effect. If that is so, it is quite a sizable tumor—extending from the left upper quadrant to the pelvis.

The laboratory work is of little help and I think we shall have to depend to a large extent on what the radiologist tells us.

DR. AUBREY O. HAMPTON I think this is the largest tumor I have ever seen if it is a tumor. The diaphragm is high on both sides. The mass is so large that the shadow extends beyond this

17-inch film The left kidney is here The outline is not very distinct, but the calyces and the kidney pelvis appear normal There is no pressure on the inner aspect of the kidney

DR KRANES Can you see the outline of the kidney?

DR HAMPTON I cannot see it in any of these films, but all the films are not here

DR KRANES I was relying on that a good deal

DR HAMPTON The kidney outline here is very indefinite I do not know whether you can rely on this shadow, but you can be sure of the fact that the calyces and pelves are normal, and I cannot imagine a tumor of this size primary in the kidney without deformity of the kidney pelvis or calyces I think you can rule out kidney tumor by x-ray The fundus of the stomach is on the right side of the abdomen opposite the eleventh rib The stomach is displaced backward behind the right side of the spine, and in the lateral view the lower margin of the mass slants forward and downward It is not round It is more pointed below I think you can see it in these films

DR KRANES What about the statement that all the bones appeared older than they should?

DR HAMPTON That is true All the epiphyses are closed, and she was only nineteen they should not be closed until twenty-one

DR KRANES Which epiphyses?

DR HAMPTON The epiphyses of the femurs and those of the crests of the iliums

DR KRANES Do you think the dragging caused by the increased weight could have closed them?

DR HAMPTON I do not know the significance of those findings in this case

DR HORACE K SOWLES Is there anything significant about the direction of the displacement of the stomach

DR HAMPTON Yes, the fundus is displaced markedly to the right and backward

DR SOWLES Does that influence the x-ray point of view?

DR HAMPTON Yes, it does

DR KRANES In commenting on the physical examination I meant to discuss the implication, brought about by the statements about the hair growth and masculine distribution of pubic hair, that this tumor was having a masculinizing effect I am inclined to discount that since it seems to me from the description that it is no more than one would expect in many women without detectable endocrine disturbances There may, of course, be some disordered function which our present methods do not detect, but I cannot be impressed by this little evidence Furthermore,

if this were a masculinizing tumor of some sort, one would expect that the menstrual periods would have been disordered and that the 17 ketosteroid determination would have been elevated

So far as the differential diagnosis goes, there are not very many cystic tumors of the abdomen which reach this size, so that the diagnostic possibilities are immediately narrowed down The most probable cystic abdominal tumor in the female is an ovarian cyst, to which, however, there seem to be several serious objections The first is that the symptoms began in the left upper quadrant. If we pay any attention to the history,—and it seems to me we must,—I cannot see how an ovarian tumor could cause symptoms of this sort in the left upper quadrant even though it may have had a long pedicle Furthermore, I should expect some menstrual disturbances if this patient had had an ovarian tumor of this size Another thing I cannot explain on this basis is the downward displacement of the kidney Could that possibly occur with an ovarian tumor, Dr Hampton?

DR HAMPTON I have seen a retroperitoneal dermoid cyst of the ovary at the kidney level. I do not remember whether it was above or below

DR KRANES What puzzles me is that it is hard to see how an ovarian tumor could displace the kidney downward

DR HAMPTON Nor could it displace the fundus of the stomach

DR KRANES Apparently there is something about the displacement of the stomach that I do not understand

Another possibility in that location, and with downward displacement of the kidney, is an adrenal tumor But, I have never seen or heard of an adrenal tumor reaching this size or becoming cystic If such a tumor does either of these things, I am not familiar with it Statements about abnormal hair growth do not impress me in trying to support such a diagnosis

It might be a large dermoid cyst I do not believe one would get a fluid wave in a dermoid cyst, however The contents of a dermoid cyst after removal usually solidify, they are liquid *in situ*, but I do not think one would get a fluid wave. Furthermore, one should, I think, have seen some calcification by x-ray in a dermoid cyst of that size I cannot exclude it, but because there is no calcification and because of the presence of a fluid wave I think that a dermoid cyst is unlikely

Dr Hampton said he could definitely exclude a large cyst of the kidney, so I shall not discuss that any farther

The two possibilities that I should consider are,

first, a cyst of the spleen and, second, one of the mesentery or omentum. I do not know how to differentiate them, except to say that this patient's symptoms began in the left upper quadrant and that the whole story was essentially confined to that area. It would seem to me that if this were a mesenteric or omental cyst the symptoms would more likely have been in the midpart of the abdomen or lower. The displacement of the splenic flexure and kidney downward is more in keeping with a large cystic tumor originating in the left upper quadrant, most likely in the spleen. As I say except for the fact that all the symptoms were confined to the left upper quadrant, I do not see

On physical examination it was quite obvious to me that the tumor was not ovarian. We could tell that it did not extend into the pelvis but seemed to fill the whole abdomen, obviously rising from beneath the left costal margin. We therefore made a long incision and took the cyst out. In the illustration (Fig. 1) one can see the lower pole of the spleen on the left hand side where the hemostats are. Beneath that are the vessels of the pedicle. That is the point that Dr. Hampton has been describing. The x-ray films seemed to show that it ended in a rather pointed prominence which slanted down into the abdomen. The vessels of the pedicle were low. After they were freed the cyst came out easily.

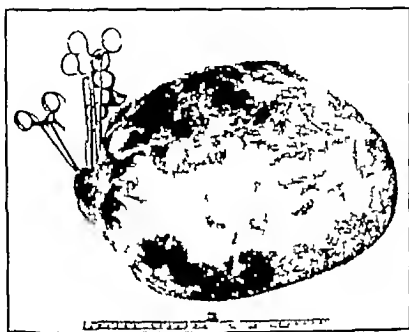

FIGURE 1. Splenic Cyst

The grayish mottled areas on the surface are foci of fibrosis.

how one could distinguish between that and a mesenteric or omental cyst. Because of that fact however, I shall make a diagnosis of cyst of the spleen.

DR. RICHARD SWEET: I was not impressed by a fluid wave on physical examination, although I did think it was a cystic tumor. Several of the other surgeons were convinced that it was a solid tumor. Having seen with Dr. Daniel F. Jones two other cases of cyst of the spleen with the absolutely characteristic findings which this girl showed including those found in the x-ray films and on physical examination of the abdomen, we made a preoperative diagnosis of cyst of the spleen.

CLINICAL DIAGNOSIS

Cyst of the spleen

DR. KRANES'S DIAGNOSIS

Cyst of the spleen

ANATOMICAL DIAGNOSIS

Cyst of the spleen.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: This cyst weighed 17 kilograms (38 pounds) and is the largest of the four splenic cysts that we have had here. It was unilocular and filled with hemorrhagic, somewhat chocolate-colored, thin fluid. The splenic tissue was stretched thinly over the cyst, but was otherwise normal. On microscopic examination we could not find any epithelial lining, and from the reports in the literature* only a few show such a lining. Of the other three cysts of the spleen that we have seen one was a dermoid cyst lined with stratified squamous epithelium, the other two showed contents similar to those in this case and had no epithelial lining, just connective tissue. The etiology of these cysts of the spleen is unsettled: some are angiomatous and are true neoplasms, a few are probably congenital, but most people believe that the large proportion of them are traumatic.

*Fowler, R. H. Cystic tumors of the spleen. *J. Intern. Med.* 46: 249, 1913-14.

PROLONGED RESIDENCIES THEIR EFFECT ON HOSPITALS

THE first of the problems raised by prolonged residencies—that of their effect on medical education—was discussed in the June 13 issue of the *Journal*. The second—that of their effect on hospitals and the young physicians who must go through the prolonged and rigorous training—is covered in the following paragraphs, the third—that of their effect on the practice of medicine—will be considered in a subsequent issue.

By enrolling the young medical graduate for five years at such a crucial period of his development the hospitals assume a tremendous responsibility. This period of training must be made a well-rounded educational experience, and clinical duties must be limited sufficiently to make this possible.

Practical experience must be supplemented by additional, specialized education in basic science, and if the medical schools fail to co-operate, the hospitals must become little universities in themselves. Few, if any, not directly associated with medical schools are in a position to meet such a demand at the present time. Even with maximal collaboration the brunt of the burden must remain with the hospitals. Since it cannot be too often re-emphasized that nothing will go farther to assure the well-being of the patient than the maximum level of competence in the resident staff, this growing function of the hospital as an educational institution must be called to the attention of the community in order that financial support will be forthcoming. Within the hospitals themselves staff-members and boards of trustees must be convinced of its importance and persuaded to make the sacrifices that will be necessary to make it effective.

When men are held for so long a period on an active service they gain clinical experience at a rapid rate. To be of real developmental value the experience must be coupled with a progressive increase in responsibility and, on the surgical services, with an opportunity to develop increasing technical skill. A greater proportion of operative procedures must go to the residents, and the visiting staff must gradually assume more of a preceptorial attitude and restrict itself sharply to the more difficult procedures. The transition period will be difficult, visiting staffs may begin to seem cumbrously large, and it will be hard to provide fair opportunity for all. The junior visiting staff is particularly in danger of being squeezed out from above and below.

On the financial side the increase in cost to the hospitals will be considerable. Quarters must be enlarged, more men must be fed, and unless resident salaries are appreciably increased, some of the most promising men will be automatically eliminated. Provision for married residents should be most seriously considered.

Still more difficult is the problem of financing

the men during periods when they have no clinical responsibilities, that is, when they are extending their acquaintance with bacteriology, pathology or biochemistry. They will be too numerous and their periods of availability will be too short to make them serviceable to the routine hospital laboratories, which are already only too often over crowded. They will require active tutorial supervision, and funds will be needed both to pay the tutors and to provide fellowships for those who could not otherwise manage this essential year.

Because of their necessary relations and responsibilities to the communities that support them, hospitals must give serious consideration to the establishment of basic internships. These should not only be suitable as foundations for further specialized training but also fit the men for general practice. The possibility of properly selecting from students still untested by clinical responsibility the men who will make in five years time the best surgeons or the best internists is dubious. Moreover, it is also doubtful if at such a period in their careers students should be asked to make a choice that can be revoked only with difficulty. With so-called "straight internships" a start in the wrong direction will be almost prohibitively time-consuming. Yet many of the present leaders in the profession required two or more years of hospital experience before they were able to decide in which branch of medicine they belonged.

One more danger must be cited. With five years residence in a single institution, with the inevitable selection of the majority of the visiting staff from the products of its own resident system and with the appointment of residents largely limited to the students who have worked on the wards, there is peril of intellectual inbreeding. Even at the sacrifice of considerable administrative convenience, every effort should be made to exchange men with other institutions at all levels of training and experience, in order partially to counteract this tendency.

ROBERT THEODORE GUNTHER AND THE HISTORY OF SCIENCE

ALTHOUGH there have been many historians of medicine and various other branches of science, such as mathematics, few men have devoted their lives to the history of science at a whole. In America the outstanding example is Professor George Sartori, of Harvard University, the author of the scholarly three volume *Introduction to the History of Science* now complete up to the fourteenth century, with a final volume nearly ready for the press. In addition, he has edited over thirty volumes of the periodical *Isis* the leading journal in its field. Sartori's scope knows no bounds in science, for his writings cover all science from astronomy to zoology. His encyclopedic mind can only be compared to those of the great humanists and scholars of the Middle Ages and Renaissance, who took all knowledge as their province. Others, however, have toiled profitably in a narrower field, and such a one was Robert Theodore Gunther, through whose death on March 9 the history of science loses an active worker.

Gunther was the eldest son of a distinguished father, Albert C. L. Gunther who came to England from Germany on a visit in 1856. He viewed the large but unsystematized collection of zoological material at the British Museum and, expressing the need for organization, was invited to begin work at once. His efforts were so appreciated that he soon was made director of the Zoological Department. He worked in the museum steadily and almost daily from 1856 to 1895 under his supervision the collections more than doubled in size. Gunther became the leading systematic zoologist of his day recognized throughout the world as eminent in his field. To this great scientist and to Roberta McIntosh of St. Andrews Scotland, a son, Robert, was born, who, in turn was to distinguish himself in quite another field of science.

Born in 1869, young Gunther was educated at University College in London and later at Mag,

dalen College in Oxford. In the latter institution, as fellow and tutor, he served all his mature years. Oxford became his home, and his work centered around the great university. During the World War he began collecting, cataloguing and photographing the numerous scientific instruments scattered in the various colleges and museums in Oxford. A number of early catalogues were published, but his most enduring work was not inaugurated until 1923, when he published the first of a long series of books on *Early Science in Oxford*. The last, Volume XIII, was issued in 1938. A companion volume, *Early Science in Cambridge*, was issued in 1937, *Early Medical and Biological Science* (1926) was an extract of particular medical interest from the larger series on Oxford. The works were all privately printed for subscribers by the Oxford University Press and are splendid examples of fine typography. The whole series was a monumental accomplishment—factual, detailed, extensively illustrated, scholarly and in every way a credit to the history of science. No detail was too small to be noticed by Gunther, who turned out from the dusty corners of the halls, museums and libraries of Oxford a surprising amount of interesting and informative material. Of particular importance is the printing from manuscript of the *Transactions of the Philosophical Society of Oxford, 1683-1690*, in Volume IV of the Oxford series, Chaucer's *Treatise on the Astrolabe* in Volume V, a facsimile and translation, by K. J. Franklin, of the *Tractatus de Corde* by Richard Lower in Volume IX, and numerous works of Robert Hooke, including *Micrographia*, in Volume XIII. Books of particular interest to medical men are, in addition to Lower's *Tractatus de Corde*, *The Biological Sciences* (Volume III) and *Oxford Colleges and Their Men of Science* (Volume XI). Gunther wrote and edited many other books, including *Early British Botanists*, *The History of the Daubeny Laboratory*, *The Architecture of the Hospital of St. John* and a series of smaller volumes entitled *Old Ashmolean Reprint*.

In addition to the books, of which the list given above is not by any means complete, Gunther worked for years to establish a museum in Ox-

ford worthy of the history of science. The natural site was the Old Ashmolean, a beautiful building with a superb portal designed by Christopher Wren. After considerable opposition this building was secured as a permanent science museum, and it now contains the great collection of scientific instruments found in Oxford by Gunther and those given to the university by Lewis Evans. In May, 1927, the building was opened. A fine memorial window was added to commemorate the men of science who were connected with the original foundation of the museum—Tradescant, Plot, Ashmole and Wren.

An admirable chance to display these scientific instruments was taken advantage of by Sir William Osler in the summer of 1919, when he gave his presidential address before the Classical Association at Oxford on "The Old Humanities and the New Science." Gunther spread his treasures before the eyes of the classicists in the picture gallery of the Bodleian Library, and before his friends in quite another field of endeavor, with a light touch Osler dilated on the historical value of these complicated instruments. That he succeeded in interesting the classicists goes without question, but a large share of the success of the exhibit depended on Gunther. A catalogue of the exhibition was issued at the time, and reference to the event was recalled by Harvey Cushing in the American edition of Osler's address, published in 1920.

Gunther, in general, was a lone worker and never a type of individual who could be popular with his fellow men. He wrote and edited almost continuously, most of his books were issued from his own home on Folly Bridge in Oxford. He was, however, a prompt and business-like correspondent, and a loyal friend to all those who saw the value of his work. To others, and there were unfortunately a good many of them, he seemed rather distant and diffident. His name will go down in history as that of a man who made a definite contribution to the history of science, for he unfolded for his contemporaries, and those that will come after them, the history of the development of science in Oxford as no one had done before him.

MEDICAL EPONYM

CARREL DAKIN SOLUTION

Alexis Carrel, of the Rockefeller Institute, and Henry C Dakin, of the Herter Laboratory, New York City, while working in the laboratories at Compiègne, supported by the Rockefeller Institute for Medical Research and attached to Hospital 21 of the French Army, published the results of their collaboration in 1915. In the *Bulletin de l'Académie de médecine* (74 [3S] 361-368 1915) appears an article entitled *Traitement abortif de l'infection des plaies* [The abortive treatment of infected wounds]. The author is given as Alexis Carrel, national correspondent of the Academy of Medicine, with the collaboration of Dakin, Daufrèsne, Dehelly and Dumas. A description of the technic of the use of this solution is given. A translation of their conclusions is as follows:

It is thus possible to sterilize infected wounds and to heal them like aseptic wounds. It would seem that the abortive treatment of infection may considerably hasten the healing of an infected wound and prevent the greater part of those complications which cause death, the amputation of extremities and other more or less severe crippling.

Dakin published an article "On the Use of Certain Antiseptic Substances in the Treatment of Infected Wounds" in the *British Medical Journal* (2 318-320, 1915). He gives full directions for preparation of the solution and concludes:

It has been possible to prepare a simple hypochlorite mixture which maintains approximate neutrality under all conditions, is practically non-irritating and which, when properly applied has given most encouraging results in the antiseptic treatment of wounds.

PYELITIS IN PREGNANCY

Mrs H., a twenty eight year old primipara twenty five weeks pregnant came into the office on April 10 1939, complaining of right sided pain. The right kidney was tender, the temperature was 101°F, the pulse 120. A diagnosis of pyelitis

was made, and the patient was advised to enter the hospital.

The family history was negative. The patient's past history included "cystitis," measles and chicken pox. She had undergone a tonsillectomy and an appendectomy. In 1938 she had been hospitalized for three days with a carbuncle. Catamenia began at thirteen, were regular with a twenty eight-day cycle and lasted three days. The last period was October 16, 1938, making the expected date of confinement July 23. She was first seen in February 1939, at which time a physical examination was entirely normal.

The patient was admitted to the hospital on April 11 with a temperature of 103°F and a pulse of 140. On April 12, following a chill, the temperature rose to 105°F and the pulse to 130. The next day the temperature rose to 105°F from a low of 98. A catheter specimen showed *Bacillus coli* on culture. Blood examination on April 14 showed a red-cell count of 2,820,000 with 55 per cent hemoglobin. She was started on iron therapy.

On April 15 the urine was macroscopically bloody and an intravenous pyelogram showed that excretion from the right kidney was slow, the best plate occurring two hours after injection. A consultation was held with a urologist. The question of sulfanilamide therapy was raised but because of the anemia it was thought to be contraindicated. On April 17 when the temperature was coming down—the highest point on that day being 100°F—and the bloody urine had ceased a cystoscopy was performed and the right kidney catheterized, a No. 9 catheter being easily placed in the renal pelvis. The bladder was free from inflammation. The residual urine from the right kidney totaled 22 cc. The kidney pelvis was washed out with boric acid solution and left full of the solution. On April 19 the temperature rose to 102°F but came down to normal eight hours later, where it remained until discharge on April 29. A blood examination on April 28 showed the red-cell count to be 3,690,000 with a hemoglobin of 69 per cent.

The pregnancy from then on was normal and uneventful. There was no recurrence of the pyelitis. The patient was delivered on July 19 and made an uneventful convalescence.

Comment. This case well illustrates the possible severity of an acute attack of pyelonephritis. It also shows the attitude of the consultant toward the use of sulfanilamide in the face of the anemia; it was believed unwise to resort to chemotherapy.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

The cystoscopy was done in order not only to wash out the kidney pelvis but also to rule out any bladder disease in the face of occult blood in the urine. It is not correct to claim that the kidney lavage cured this patient. It is perfectly fair to say that it helped her, but one cannot deny that sulfanilamide might have resulted in just as spectacular a recovery.

Occult blood in the urine demands diagnosis. Sometimes the bleeding comes from congestion of the bladder itself. In this case the bladder was normal and the bleeding came from the acute infection in the renal pelvis. If sulfanilamide becomes a household remedy, some cases of renal disease that can be diagnosed only by intravenous pyelograms, cystoscopy and catheterization of the renal pelvis will be overlooked. The striking cures that will be seen following its use must not interfere with consultations with well-trained urologists when hematuria exists.

MISCELLANY

RESPONSIBILITY FOR MEDICAL CARE OF THE INDIGENT SICK

At the 1938 Massachusetts Conference of Social Work the Committee on Next Steps in Medical Care* considered the medical care of the indigent, and adopted the following principles:

1 An indigent person is defined as one unable to provide for himself the ordinary necessities of life (food, shelter, clothing and so forth), including medical care when ill.

2 A medically indigent person is one who is ordinarily self-supporting at a subsistence level but unable to pay for medical care when ill.

3 The committee subscribes to the principle that the medical care of the indigent is a relief problem and that, as such, it is the final responsibility of government. Voluntary hospitals and health agencies should continue to care for members of this group so far as their funds will permit, but to the extent to which voluntary resources are inadequate, medical care for this group should be provided from tax-supported funds.

4 The committee believes that the medical care of the medically indigent is also a relief problem. It believes that medical care of persons in this group is the joint responsibility of voluntary and public agencies and that the decision as to whether the responsibility is private or public should be made in each individual case by mutual agreement after adequate social investigation.

5 The committee further subscribes to the principle that the medical care of persons in the low-income brackets, at or above the level of self-support, is an insurance problem, which may be solved through the

development and operation of voluntary prepayment insurance plans. Should the development of such plans not constitute a sufficiently wide or adequate coverage of members of this large group, the alternative may lie in compulsory insurance, similar in operation to unemployment compensation under the Social Security Act.

At the conference held on November 8, 1939, the committee restricted its deliberation to the medically indigent, that large group of the population ordinarily self-supporting but unable to pay for medical care when ill. The following additional statement of principles was formulated by the committee and approved by the conference:

1 The medical care of the medically indigent is the joint responsibility of tax-supported and voluntary agencies. The medical needs of this otherwise self-supporting group are not being met. Provision of better medical care for these individuals is the common goal of voluntary agencies, the medical profession and public officials concerned with health and welfare. The achievement of this common purpose requires the joint effort and sincere co-operation of all concerned to develop a complete well rounded program.

2 The decision as to whether a tax supported or voluntary agency should bear the cost of this care should be made by persons competent to evaluate the medical, social and economic aspects of each case. This decision might well be based on the principle that the care of an illness constituting only a temporary disability belongs to the voluntary agency, and the care of an illness which produces disability of long or permanent duration falls more logically within the responsibility of the tax supported agency. This principle should be interpreted to designate not the place of treatment but rather the responsibility for the cost of care.

3 The maintenance of this service would entail cost and personnel not at present supplied through either governmental or voluntary channels.

4 The committee therefore recommends the formation of a permanent committee to plan for the co-ordination of medical services among the governmental agencies, the voluntary agencies and the medical profession, to the end that adequate medical care may be available to all these groups.

TUBERCULOSIS IN ADOLESCENTS

For the past few years vast numbers of school children and college students have been tested with tuberculin and the x ray. Out of these studies have come some definite conclusions pertaining to the incidence of tuberculosis in youth. Little has been reported, however, about the outcome of cases discovered in mass-testing programs, doubtless because sufficient time has not elapsed in most of these studies to justify an appraisal of the results of treatment. In Massachusetts, where pioneer work in mass case finding was begun more than a decade ago, Chadwick and Evarts (Treatment of pulmonary tuberculosis in adolescents *Am Rev Tuberc* 41:307-318, 1940) have attempted to evaluate the results of various types of treatment and the fate of tuberculous adolescents. A summary of their findings follows:

The case fatality rate of pulmonary tuberculosis cannot be determined unless we follow a large number of cases from the time diagnoses are made until the death of all the individuals concerned. Unlike acute communicable diseases, tuberculosis is a disease of long duration. It may

*The members of the committee are: Frank E. Wing, chairman; Mrs. Selma Bridges, Dr. Allan M. Butler, Edith R. Canterbury, Mary Alma Cotter, Frank Goodhue, Dr. Alton S. Pope, Arthur J. Strawson and Margaret H. Tracy, secretary.

be acute but is more often chronic, with periods of quiescence followed by exacerbations, and may so continue for years.

We may, however, measure the effect of treatment by checking against each other groups of patients of similar age who have been treated by different methods for the same length of time. The authors studied the records of 745 patients who had parenchymatous pulmonary tuberculosis at the time they came under observation. Most of them received treatment in some sanatorium. These were divided into three groups according to the time they had been under observation—namely Group A, from 5 to 10 years; Group B from 3 to 5 years; Group C, less than 3 years.

The type of treatment received by these groups, further divided according to stage of disease, was found to vary during the past ten years. There was a trend away from routine bed-rest treatment for a preliminary try-out period to be later supplemented by pneumothorax if the disease were not controlled. The present practice is to institute pneumothorax promptly. The minimal cases of Group A admitted to Middlesex County Sanatorium (prior to 1934) received no immediate treatment with pneumothorax; 40 per cent of Group B were given pneumothorax promptly; of Group C, 87 per cent were given pneumothorax soon after admission.

The conclusion of the authors, based on their own studies and supported by those of others, are that the mortality from tuberculosis in adolescents is high and treatment very discouraging. Morgan, reporting in 1938 on 320 cases of boys and girls ten to eighteen years of age treated in a sanatorium prior to 1933 found that 62 per cent were dead, 14 per cent under treatment, 17 per cent well and 7 per cent not located. The treatment in this series consisted of prolonged bed-rest supplemented by pneumothorax in a few cases, and then given only after a period of waiting. Zacks recently studied 186 cases treated in sanatoriums and observed for a period of about four years. Those that had routine sanatorium treatment only showed a mortality of 30.9 per cent for boys and 34.4 per cent for girls; those that had sanatorium treatment plus pneumothorax showed a mortality of 8.5 per cent for boys and 23.1 per cent for girls. In the authors' group observed for five to ten years the deaths were 4.8 per cent for the boys and 27.5 per cent for the girls. Half these cases were given pneumothorax.

Pneumothorax should be instituted as soon as possible after diagnosis is made even in the minimal cases, and this should be supplemented by pneumonolysis if satisfactory collapse is prevented by adhesions that can be cut. Ineffective pneumothorax should be abandoned, and some other surgical collapse procedure carried out. When a satisfactory collapse with pneumothorax is obtained, it should be continued for a minimum of three years, and for five years in the cavity cases.

Patients discharged from the sanatoriums should be considered as having completed only the first phase of treatment and should return at frequent intervals for consultation during subsequent years. If they are pneumothorax cases, they will have their refills and in any event their condition will be rechecked. A roentgenogram taken every three months will be the most important means of following the course of the disease. If the old lesion shows reactivation, or a new one appears, prompt readmission and suitable treatment should be instituted.

The evidence available in this and other studies indicates the ineffectiveness of bed-rest treatment alone in staying the progress of tuberculosis in adolescents.—Reprinted from *Tuberculosis Abstracts* June 1940.

MAINE NEWS

ANNUAL MEETING OF THE MAINE MEDICAL ASSOCIATION

The program of the annual meeting of the Maine Medical Association, to be held June 23, 24 and 25 at Rangeley Lakes, is as follows:

MONDAY, JUNE 24

MORNING SESSION—Conferences.

Ophthalmology W. H. Chaffers, M.D., Lewiston, chairman.

1. Some Oculomotor Disturbances. David G. Cogan, M.D., Cambridge, Massachusetts.
2. The Diagnosis and Treatment of Some Corneal Conditions. Trygve Gundersen, M.D., Boston.

Pathology Mortimer Warren, M.D., Portland, chairman.

1. Discussion of Laboratory Methods in Tuberculosis Work. Lester Adams, M.D., Hebron.
2. Discussion of Medical Mycology. Leon Balaban, M.D., Portland.
3. Demonstration of specimens, slides and case reports.
4. Consideration of the advisability of forming a state association of pathologists.

Surgery Harrison L. Robinson, M.D., Bangor, chairman.

Round-table discussion of the "acute abdomen" and other surgical emergencies.

Anesthesia Maurice E. Lord, M.D., Skowhegan, chairman.

1. Anesthesia from the Surgeon's Viewpoint. G. E. Young, M.D., Skowhegan.
2. Anesthesia Then and Now. S. E. Sawyer, M.D., Lewiston.
3. Why Should the Physician Anesthetist Be Employed as Chief of the Anesthesia Department in Every Hospital? E. M. Fuller, M.D., Bath.
4. Anesthetic Emergencies, Complications and Treatment. Eugene Brown, M.D., Bangor.
5. Anesthetic Risks with Reference to Choice of Agent. Gilbert Clapperton, M.D., Lewiston.
6. Pentothal Sodium: Its field of usefulness. R. M. Towell, M.D., Hartford, Connecticut.
7. Anesthesia and Disturbed Physiology. Meyer Saklad, M.D., Providence, Rhode Island.

Medicine James W. Reed, M.D., Farmington, chairman.

1. Diabetes: The problem from the standpoint of the internist. Sven M. Gunderesen, M.D., Hanover, New Hampshire.
2. Diabetes: The problem from the standpoint of the surgeon. Harry Brinkman, M.D., Wilton.
3. General discussion directed by E. R. Blausdell, M.D., Portland.

Obstetrics R. B. Moore, M.D., Portland, chairman.

1. Indications for and Some Methods of Induction of Labor. Leroy C. Gross, M.D., Lewiston.
2. Routine Episiotomy and Use of Low Forceps in Primiparas. Clarence Emery Jr., M.D., Bangor.
3. Management of Posterior Positions. E. A. McLean, M.D., Portland.
4. Discussion of general obstetrical problems.

Pediatrics A W Fellows, M.D., Bangor, chairman

- 1 The Newer Remedies and the Administration of Fluids F P Webster, M.D., Portland
- 2 Symptomatic Treatment. C S Bauman, M.D., Waterville.
- 3 Immunization and Specific Serums Alice S Whittier, M.D., Portland
- 4 General Principles and Technic of Medication A W Fellows, M.D., Bangor

AFTERNOON SESSION—Clinicopathological Conference Julius Gottlieb, MD, chairman.

Discussion Dr Reginald Fitz, M.D., Boston

TUESDAY, JUNE 25

MORNING SESSION—Conferences

Medicolegal Medicine W S Stinchfield, M.D., Skowhegan, chairman

Timothy Leary, M.D., Boston, and Attorney General F U Burkett, Portland, will address this meeting

Nervous and Mental Diseases F C Tyson, M.D., Augusta, chairman.

- 1 Psychotherapy in General Medical Practice M R Kaufman, M.D., Boston.
- 2 The Rorschach Test in Diagnosis of Psychoses and Psychoneuroses A A Weil, M.D., Augusta
- 3 Use of Intelligence Tests in Diagnosis of Psychotic Patients. G R Foster, Ph.D., Augusta
- 4 Summary of Two Years' Experience with Insulin in the Treatment of Certain Psychoses E. A Blank, M.D., Bangor

Medicine F A. Winchenbach, M.D., Bath, chairman.

Head Injuries The responsibility of the general practitioner, initial treatment, differential diagnosis, treatment of non surgical groups, treatment of surgical groups, prognosis A panel discussion by Drs M. E. Joss, Richmond, G A. Gregory, Boothbay, W B Mitchell, Wiscasset, W V Cox, Lewiston, and H. E. MacDonald, Jr., Portland

Surgery C H. Jameson, M.D., Rockland, chairman.

- 1 Estimating the Surgical Risk. E E O'Donnell M.D., Portland.
- 2 Pitfalls of Surgery E H. Rusley, M.D., Waterville.
- 3 Choice of Anesthesia. Gilbert Clapperton, M.D., Lewiston.
- 4 Postoperative Management. W V Cox, M.D., Lewiston.
- 5 Safeguarding the Surgeon. Attorney H E Locke, Augusta

Ear, Nose and Throat F T Hill, M.D., Waterville, chairman.

Recent Advances in Otolaryngology

- 1 The External Ear Pierre Provost, M.D., Augusta.
- 2 The Middle Ear and Mastoid. W A. Ellingwood, M.D., Rockland.
- 3 Meniere's Disease. P J Mundie, M.D., Calais
- 4 Chemotherapy in Sepsis in Otolaryngology E. R. Irgens, M.D., Waterville.
- 5 Paranasal Sinuses R. M. McQuoid, M.D., Bangor
- 6 Allergy in Otolaryngology C H Gordon, M.D., Portland.

7 The Pharynx and Larynx. G O Cummings, M.D., Portland

8 Neoplasms Involving the Ear, Nose and Throat A C Hurd, M.D., Gardiner

Gynecology A P Leighton, M.D., Portland, chairman.

- 1 Eclampsia and Its Treatment. W F W Hay, M.D., Portland
- 2 Vaginal Discharges Their significance and treatment. T C Bramhall, M.D., Portland.

ATMOSPHERIC RAGWEED POLLEN SURVEY FOR 1939

In Portland, glass slides were exposed for fifty consecutive days on the roof of the Maine General Hospital, under the supervision of the pathologist, Dr Mortimer Warren. The highest count was on September 2, the number of "hay-fever days" (count of 25+) was ten, the pollen index (Durham) was 14. In Camden the receiving station was placed at the CCC camp, under the supervision of the Maine Health Bureau. The fifty-day season, from August 10 to September 28, showed the highest count on September 3, the number of "hay-fever days" was seventeen, the pollen index was 26. After a re-check Mr O C Durham stated that the Camden figures were higher than anything he had had from Maine. In answer to the question as to how to account for this, Dr C. B. Sylvester, who is in charge of the Pollen Survey, stated that more ragweed was found in the vicinity of the CCC camp than anywhere else around Camden and that the soil should be planted with some worthwhile cover, otherwise ragweed would flourish unbroken turf does not grow ragweed.

RECOMMENDATIONS OF THE ADVISORY COMMITTEE ON SYPHILIS CONTROL

This committee has recommended that a uniform system of records be adopted in all treatment clinics and that a duplicate copy be filed at the office of the Bureau of Health. It also recommends that drugs distributed by the Bureau of Health to physicians and clinics for the treatment of syphilis be limited to the following preparations: mercury cyanide, sulfarsphenamine, Tryparsamide, bismuth subsalicylate in oil, Bismarsen, distilled water, Mapharsen and neoarsphenamine.

In going over the records of the bureau a 12 per cent increase in blood examinations was noted during the fiscal year—a hopeful sign. There are at present twenty-nine clinics in the following cities: Augusta, Bangor, Bath, Belfast, Biddeford, Bingham, Calais, Danforth, Eastport, Ellsworth, Grand Isle, Guilford, Houlton, Island Falls, Lewiston (2), Millinocket, Old Town, Portland (3), Presque Isle, Rockland, Rumford, Sanford, Skowhegan, Waterville, Wilton and Winthrop.

CORRESPONDENCE

DEPRIVATION OF LICENSES

To the Editor The license of Dr Joseph D Beuparant, 528 Eastern Avenue, Fall River Massachusetts, was revoked by the Board of Registration in Medicine on June 6 because of conviction in court of abortion and that of Dr James B. Ryan, 53 Maple Street, Easthampton Massachusetts, was suspended on the same date because of drug addiction and violation of the Harrison Narcotic Law

REPORTS OF MEETINGS

EDWARD K. DUNHAM LECTURES

The Dunham Lectures at Harvard Medical School for 1940 were delivered by Dr S. Walter Ranson professor of neurology and director of the Institute of Neurology Northwestern University Medical School Chicago.

The first lecture on March 4 was concerned with "The Hypothalamus and the Sympathetic Nervous System." In experiments on cats the hypothalamus was stimulated a procedure which resulted in an elevation of blood pressure, an increase of the rate and depth of the respirations, dilatation of the pupils and an increased bladder tension. All except the last phenomenon which must be regarded as parasympathetic, were held to result from stimulation of the sympathetic centers. Accurate localization of the stimulus demonstrated that the best effect was obtained from sites in the lateral areas of the hypothalamus and around the fornix, but not in the internal capsule. The bladder contraction mechanism was further localized near the anterior commissure. The path of the fibers was considered to descend through the central gray matter and tegmentum of the midbrain and the anterolateral part of the cervical cord.

In an attempt to determine the role of the hypothalamus in the regulation of body temperature, bilateral lesions were placed in various parts of the hypothalamus in cats and tests were subsequently made of their ability to withstand environmental heat and cold. In other experiments localized heating with a high-frequency current was used to locate the part of the brain which is specifically responsive to heat and presumably activated by the warmth of the blood when the temperature of the body rises too high. Dr Ranson concluded that there are two thermoregulatory centers at the base of the brain. In the preoptic and subpreoptic regions is a center which is sensitive to heat and prevents overheating by activating a more caudally situated panting center. The pathway connecting the heat sensitive center with the panting center runs through the lateral hypothalamus. The center which by conserving body heat prevents chilling is coextensive with the sympathetic center in the hypothalamus. Large bilateral lesions in the caudolateral part of the hypothalamus interrupt the descending pathway from both these centers and result in persistent lack of ability to adjust to both heat and cold. Medially placed lesions had very little effect on temperature regulation.

In considering the significance of these findings for man Dr Ranson reminded his audience that the only difference in man is his ability for rapid loss of heat through sweating his production and maintenance of

heat are essentially the same as those for animals. Work on monkeys indicated that the hypothalamic centers are essentially the same as those in the lower animals, at least so far as the center for the conservation of heat is concerned.

As to how indispensable such a hypothalamic temperature regulating center is, Dr Ranson stated that although some control exists in the spinal animal, such preparations cannot respond as well to sudden marked changes of temperature as they can to slow slight changes.

In conclusion Dr Ranson stated that the central control for the sympathetic nervous system lies in the caudolateral areas of the hypothalamus at the level of the tuber cinereum and mammillary bodies and integrates the system into purposeful patterns. Thus, on exposure to cold, there is a resultant vasoconstriction, fluffing of the hair and increased heat formation, all of which can be prevented by lesions suitably situated.

On March 6 Dr Ranson discussed "Hypothalamico-hypophyseal Relations." Since the functions of these two organs that are so closely related anatomically have been associated, and since Wislocki has shown a lack of blood drainage from the pituitary gland to the hypothalamus, an attempt was made to determine the nature of the interrelation.

It is known that the nerve fibers connecting these two structures form two bundles, called the supraoptic-hypophyseal and tuberohypophyseal tracts. Numerous experiments revealed that it was only lesions of the former fibers which caused diabetes insipidus and also resulted in atrophy of the supraoptic nucleus and neural lobe of the hypophysis. The resultant disease had two phases, a temporary one for four or five days and the permanent stage developing about a week later. The polyuria regularly preceded the polydipsia.

In the rhesus monkey it was demonstrated that the severity of the diabetes insipidus was proportional to the amount of the neurohypophysis which was left intact above the level of the transection of the supraoptic-hypophyseal tract in the medial eminence or the neural stalk. Such lesions cause degeneration of the neurohypophysis and of the supraoptic nucleus. Microscopic and macroscopic examinations, as well as hormonal assay and substitution therapy indicate that it is the failure of the neurohypophysis that causes diabetes insipidus, yet a hypophysectomy fails to produce the syndrome. Dr Ranson suggested that the two findings can be correlated by hypothesizing the necessity for leaving the anterior lobe of the pituitary gland intact.

Dr Ranson cited cases of this disease in man studied post mortem in which destruction of the supraoptic nucleus, the supraoptic-hypophyseal tract or the neurohypophysis resulted in destruction of all three members of the closely integrated system.

The speaker went on to discuss the question of the effect of the hypothalamus on the anterior hypophysis. Anatomically few fibers can be demonstrated connecting these regions. Yet hypothalamic lesions may simulate the antidiuretic effect of the anterior lobe of the pituitary gland, although section of the neural stem does not result in hypoglycemia or insulin sensitivity.

In regard to adipogenital dystrophy Dr Ranson indicated that the adiposity may result from a hypothalamic lesion, and the genital dystrophy from the anterior pituitary lesion. In order however to produce obesity in rats, enormous bilateral lesions around the third ventricle were necessary and this condition was even more difficult to produce by hypothalamic lesions in monkeys. The small

est effective lesions were in the ventromedial, the dorso-medial and the arcuate nuclei. No macroscopic effect on the pituitary gland or its stalk was noted, and microscopic studies are not as yet complete. The removal of the hypophysis after a week seemed further evidence that this organ is not necessary for the typical obesity changes.

That the hypothalamus may also have some relation to the gonadotropic hormones was indicated by ventral lesions near the optic chiasm and infundibulum, which resulted in sterility and impotence associated with varying degrees of atrophy of the internal and external genitalia. Those in the largest group were anatomically normal, but failed to exhibit typical estrous behavior. Dr. Ranson concluded that a center of the hypothalamus near the optic chiasm is necessary for the mating reaction in guinea pigs, despite a normal sexual cycle and an intact pituitary gland.

The final paper of the series, on March 8, was concerned with "The Hypothalamus and Behavior." Dr. Ranson alluded to the "sham rage" of Cannon's decorticate cats and to the work of Bard suggesting the need for the posterior hypothalamus for the expression of emotion. It was shown that stimulation of the hypothalamus results in part of the rage pattern—dilatation of the pupils, rapid respiration and elevated blood pressure—while under ether, and the whole response following recovery from anesthesia. Destruction bilaterally, on the other hand, caused somnolence, lethargy and a tendency to catalepsy in cats. The initial somnolence wore off gradually, but there was a persistent lack of motor initiative. The monkeys with such lesions were somnolent but not comatose, they were emotionally stolid. Many of them showed hypothermia, but this was not responsible for the somnolence. One animal showed classic catalepsy.

Lesions of the thalamus, subthalamus and anterior hypothalamus failed to cause somnolence, as did also an interruption of the paths to and from the thalamus and cortex.

As a result of the findings, Dr. Ranson discussed the mechanism of sleep. Although disclaiming knowledge of the mechanism for falling asleep, it was predicted that the means of maintaining a proper balance between the sleeping and the waking states reside in a hypothalamic waking center, independent of the cortex. Evidence pointing in the same direction is found in von Economo's studies of encephalitis lethargica in man. He reported that lesions in the posterior part of the floor of the third ventricle result in somnolence, while lesions situated farther forward, near the globus pallidus, may result in insomnia. The experimental lesions merely serve to reproduce and localize a long known fact and to emphasize the necessity for the integrity of a waking center. The transient character of these manifestations of posterior hypothalamic lesions suggests that despite its great importance, this part of the brain is not the only center for controlling emotional behavior and for maintaining the waking state.

Dr. Ranson stated that tumors of this region in man may cause mania or alternating irritability and unreasonableness with somnolence. Furthermore, operations around the third ventricle have caused lively mania, whereas manipulation of the lateral ventricles or the caudate nucleus results in no such symptoms.

In summary, Dr. Ranson stated that the hypothalamus serves to activate the sympathetic nervous system and to integrate its activity into purposeful patterns, that it maintains the internal secretions of the neurohypophysis and may have some effect on the anterior lobe of the pituitary gland and, finally, that it plays an important part in the expression of emotions and in the maintenance of the waking state.

TUFTS COLLEGE MEDICAL ALUMNI LECTURE

The annual alumni lecture of the Tufts College Medical School was delivered on April 3 by Col. G. R. Callender, director of the Army Medical School, who spoke on "Diarrheal Diseases."

Dr. Callender gave a résumé of the historical background of the diarrheal diseases and then discussed some important aspects of each type of infection. Concerning the epidemiology of amebic dysentery, it was stated that water, since it is rarely a cause, should not be blamed until food, fingers and flies have been eliminated as carriers. Some recent investigations, however, have raised doubt as to the complete efficacy of the usual concentrations of chlorine used in water purification against the cystic form of the ameba.

Dr. Callender contrasted the symptoms and pathological findings in bacillary dysentery with those of the amebic variety. In the latter disease symptoms and laboratory findings are usually minimal until secondary invaders enter the small, scattered ulcers. This superimposed infection, it was pointed out, may be caused by one of the dysentery bacilli. Bacillary dysentery, on the other hand, is an acute infectious disease, with characteristic systemic response and laboratory findings and with widespread pathologic changes of the intestinal tract. The passage of a stool in this disease is painful, whereas there is usually little discomfort in uncomplicated amebic dysentery.

In discussing food poisoning, Dr. Callender stated that some of the staphylococci that are recovered from cases of food poisoning will grow at 8°C., especially if they have been previously warmed for a few hours. Many household refrigerators are operated at even higher temperatures than this. These organisms may also thrive in mediums containing the same ingredients in the same strength as are in the brine used to pickle hams before smoking. The early symptoms in cases of staphylococcal food poisoning are epigastric pain and vomiting, diarrhea may follow later.

No inflammatory exudate has been seen in the diarrhea of the condition which is called "intestinal influenza."

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next written examination and review of case histories (Part I) for Group B candidates will be held in the various cities of the United States and Canada on Saturday, January 4, 1941, at 2:00 p.m. Candidates who successfully complete the Part I examinations proceed auto-

matically to the Part II examinations held later in the year. Applications for admission to Group B Part I examinations must be on file in the secretary's office not later than October 5, 1940.

The general oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted by the entire board meeting at Cleveland, Ohio, immediately prior to the 1941 meeting of the American Medical Association.

After January 1, 1942 there will be only one classification of candidates, and all will be required to take the Part I and Part II examinations. For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

AMERICAN COLLEGE OF PHYSICIANS

The twenty-fifth annual session of the American College of Physicians will be held in Boston with general headquarters at the Hotel Statler on April 21-25, 1941. Dr. James D. Bruce, of Ann Arbor, Michigan, president of the American College of Physicians, will have charge of the program of general scientific sessions. Dr. William B. Breed, of Boston, has been appointed general chairman of the session. He will be in charge of the program of clinics and demonstrations in the hospitals and medical schools and of the program of panel and round-table discussions to be conducted at the headquarters.

BOOK REVIEWS

A Textbook of Surgery. John Homans. Fifth edition. 1272 pp. Springfield, Illinois, and Baltimore: Charles C. Thomas, 1940. \$8.00.

Surgery is no longer a subject that can be taught in a course or series of lecture-clinics. The student constantly encounters surgical material in his clinical experience, and often finds difficulty in crystallizing the many apparently unrelated problems. Dr. Homans' book is a great help in systematizing the conditions that need surgery for effective therapy.

The book stresses underlying principles rather than simply giving the correct diagnostic procedure and treatment for a particular disease. A historical survey of the subject is found at the beginning of each section. Then follow the anatomy and physiology of the organ, thereby suggesting to the student the fundamentals of good medical reasoning. If the reader cannot find the detail of information desired there is appended an excellent bibliography for further reference. Discussions of the surgery of the organs of special sense, of the female pelvic organs, of fractures and of the thorax serve as examples of the large field that is surveyed.

There have been many new advances in surgery since the last edition four years ago. The use of vitamin K in jaundice, the ligation of a patent ductus arteriosus and the treatment of parathyroid tetany with A.T. 10 are only a few illustrations of how this book keeps pace with recent developments. Dr. Homans has written a masterly treatise on modern surgery and is to be commended for his zeal in keeping it abreast of current progress.

Love Problems of Adolescence. Oliver M. Butterfield. 212 pp. New York: Emerson Books, Inc., 1939. \$2.25.

This book is a valuable contribution to a growing accumulation of information concerning the trends of adolescent thinking and interest, particularly as they apply to the sexual mores, and it is unique in that the information is derived from concrete questions raised by the young people themselves and is not merely an interpretation of their emotional interests as seen through the eyes of their elders.

Counselors of youth will find nothing new by way of information but much to substantiate their own experiences when confronted with love problems of boys and girls.

The introduction is concerned with a description of the study, a definition of "love problems" and a consideration of the character of the group and the modus operandi of the study. In the five succeeding chapters the author discusses the various questions which appear as the im-

mediate concern of these young people, running from means of securing dates, parental interference, night hours, chaperons and so forth, through miscellaneous behavior problems, dancing, smoking, drinking, kissing, petting, sex stimulation, masturbation, homosexuality and the social significance of menstruation and venereal disease. He found that the young people wished to discuss matters of mate selection and teen-age love, that there was an earnest desire for factual sex information, and that the trend is to think of love, sexual relations and marriage relationships as permanent.

In discussing the age factor in marriage the author emphasizes that those who recommend early marriages are so much concerned with the biological factor that they fail to give adequate consideration to the economic, sociological and psychological factors. However, he points out that studies to date have tended to negate the age factor as a means of predicting either success or failure in marriage.

Birth control and divorce appear to have been academically discussed, but the meat of the study is best expressed by the author when he says

Most of the spontaneous questions in these groups centered on the sexual aspects of marriage. Here lies the mystery of the unknown and the undiscussed. Anxiety on this score grows partly out of the labored efforts of adults to cover up this side of marriage and the persistent repetition during childhood and adolescence that any form of sexual indulgence is wrong. Uninstructed youth finds it difficult to understand how what is wrong before marriage can become the highest expression of affection in it.

The New International Clinics. Original contributions, clinics and evaluated reviews of current advances in the medical arts. Edited by George M. Piersol. Vol. 4. N. S. 2. 339 pp. Philadelphia: Montreal and New York: J. B. Lippincott Co., 1939. \$3.00.

The treatment of pneumococcal pneumonia continues to attract considerable attention, and in this volume one finds the subject approached from the chemotherapeutic and serotherapeutic angles; there is also an article on the surgical complications. In addition, there are discussions of such unusual subjects as pseudo-arteriosclerosis, vitamin K in pseudohemophilia, hepatica of childhood, and myogelosis in postural foot defects. The remainder of the volume consists of a discussion of conventional subjects, all of which round out an excellent publication.

Traité de biocolloïdologie. Tome V. *État colloïdal et médecine.* Fascicule 1. *Le Sang.* 151 pp. Fascicule 2. *Liquides et tissus organiques.* 299 pp. W. Kopaczewski. Paris: Gauthier-Villars, 1938. 160 Fr. fr.

The author of this two-volume work states that the medical profession has paid but little attention to the fundamental physical sciences and their application to the various problems of disease. He believes that studies of the behavior of the colloids will inevitably solve the riddles of human disease, provided only that the doctors learn something about them. He quotes d'Arsonval as saying "that the professors of clinical medicine are highly decorous and highly decorated individuals who ignore physics and boast about it." He states, perhaps truly, that one is struck by the general lack of comprehension by the medical profession of the basic problems of experimental medicine, by its lack of mathematical formulation of results and by its erroneous appreciation of them. In place of clear and readily established notions, it has forged a Greco-Latin nomenclature with high-sounding, pseudo-scientific facts. It is a very serious

tertaining introduction, which is capped by a lapse into poetic prose and then into poetry itself. "Following out ideas, inspired by the passion of research and by the curiosity of nature, controlled by experience, guided by the rhythm of pure reason, is to possess the palpitating life of true poetry."

After this divine introduction, one is disappointed in Chapter 1 which deals, very sketchily, with such matters as blood volume, the total red-cell count, the various blood chemical constituents and so forth. However, this disappointment is more than atoned by the conclusions, which state that since chemical and hematological data vary so greatly, it is impossible to place any credence on their results. "Ultra precise chemical methods can only result in gross errors in diagnosis, since the errors of the methods are greater than the physiological limits of the chemical studied." The author states that the physical characters of the serum and plasma tell another story.

The physical measurements which the author believes are of great importance and which have been ignored, are the density of the blood, the freezing point, the electrical conductivity, the pH, the viscosity, the surface tension, the refractive index and the rotatory power. Curiously enough, no mention is made of the sedimentation rate, a physical measurement which has become so popular. The application of these methods to the blood, spinal fluid, urine, saliva and, finally, organ extracts is indicated. The value of these methods in studying the effects of mineral waters, coffee, beer and so forth on the composition of the urine is well brought out. Aside from this, one fails—perhaps due to lack of comprehension—to get much out of this erudite work. One must conclude, therefore, that either the author is a genius far ahead of his time or he is, shall we say, misguided. Time alone will tell.

Trapping the Common Cold. George S. Foster. 125 pp. New York: Fleming H. Revell Co., 1940. \$1.25.

The author advances the theory that by following certain rules of diet, fluid intake and exercise one can be protected from attacks of the common cold. Although the reviewer cannot take exception to some of the recommendations, at least insofar as creating a sense of general well being is concerned, the book contains a great deal of physiological nonsense. There is no scientific proof of the main thesis, namely, that the common cold can be obviated in this manner.

Modern Diabetic Care. Including instructions in the diet and the use of the old and new insulins. Herbert Pollack. 216 pp. New York: Harcourt, Brace & Co., 1940. \$2.00.

This excellent manual is intended for use by diabetic patients, physicians and dietitians. The style is simple and direct, and excessive technical details are avoided. The usual chapters dealing with the nature of diabetes, the physiology of nutrition, the technique of insulin administration and the prescription of diets are included. Diabetic coma, surgery and juvenile diabetes are briefly discussed.

One may criticize his definition of diabetes—"the loss of the body's ability to burn sugars"—as being too great a simplification. The therapeutic use of alcohol for patients suffering with impaired peripheral circulation scarcely deserves mention. There is some inconsistency in prescribing diets accurately in grams and yet failing to teach patients the use of food scales, other students of diabetes have found that the use of food scales, at least for a few months, is the most dependable method of

THE EFFECT OF SULFANILAMIDE ON THE LENGTH OF LIFE OF PATIENTS WITH SUBACUTE BACTERIAL ENDOCARDITIS*

HUGH H. STRELE, M.D.†

DEADWOOD, SOUTH DAKOTA

A REVIEW of the literature concerning subacute bacterial endocarditis shows that much is yet to be learned about the etiology of this relatively common disease. Reimann¹ believes that it has been impossible to prove that the streptococcus is anything more than a secondary invader, although the work of Rosenow, in producing the disease by intravenous injection of certain strains of *Streptococcus viridans* without previous injury to the heart valves, appears to demonstrate that this organism is the primary invader in the disease. Evidence has been presented by Feldman and Trace,² among others that the disease is closely related to infection in the mouth, throat and nose. Experiments tending to prove that foci of infection in the oropharynx may be the cause of endocarditis have been performed by Welch and his co-workers,³ but others, among them Kinsella and Muether,⁴ have been unable to do this, although the two latter produced an endocarditis by the intravenous injection of *Streptococcus viridans* into dogs whose heart valves had previously been injured. They believe that the condition produced in dogs which is apparently identical pathologically with subacute bacterial endocarditis in the human subject, is dissimilar from it because of the fundamental difference between the traumatized valve of the dog and the diseased valve of the human being, and they plan a study to compare the two more closely. In general, all recent experimental work is encouraging in tone, as Graybiel⁵ has stated. Nevertheless much more must be done in order to determine the factors leading to the invasion of the blood stream, the attack on the endocardium and the failure in human beings of methods of treatment successful in experimental animals.

The treatment of subacute bacterial endocarditis, as with any disease whose etiology and pathogenesis are not understood has been carried out to a great extent on a trial-and-error basis. As new methods of combating other forms of infection have been discovered they have been applied to the treatment of endocarditis. As each has been tried, occasional reports of cures have been published then, as further work has been done, the new method has been shown to be of little value and other ideas have been put to test. It is probable that the cures credited to these methods occurred in cases of so-called benign endocarditis.⁶

With the discovery of sulfanilamide and the reports of excellent results with its use in hemolytic streptococcus infections it was at once hoped that the drug would be equally effective in the treatment of conditions in which *Streptococcus viridans* was involved. Early reports, indeed indicated that excellent results might be obtained through its use in the treatment of subacute bacterial endocarditis. One case of recovery was reported.⁷ But with the reports as to its beneficial effects came others dealing with its adverse effects. These are well set forth in the monograph of Long and Bliss⁸ who also note that cerebral toxic effects such as headache, anorexia, nausea, vomiting and dizziness, cyanosis, simple fever, dermatitis, acidosis, renal damage (the occurrence of which they question), jaundice without anemia, mild hemolytic anemia, acute hemolytic anemia, agranulocytic angina and leukemoid reactions may be observed as a result of sulfanilamide therapy. The neutropenic states resulting from the use of the drug are by far the most serious reactions covered, and reports of these have been many.⁹

In the past nine years, 76 proved cases of subacute bacterial endocarditis have been seen at the University of Chicago Clinics. The diagnosis was

From the Department of Medicine, University of Chicago Clinics.
†Formerly a student physician in medicine, University of Chicago Clinics.

based on certain criteria the presence of active endocarditis, fever, positive blood culture and embolic phenomena¹¹ Of these cases, 18 were treated with sulfanilamide In studying the effects of this drug on the course of subacute bacterial endocarditis, 4 cases were excluded* so that, for the sake of uniformity, only cases in which the *Streptococcus viridans* was grown on blood culture might be considered The 14 remaining cases were studied in order to determine the effect of the drug on bacteremia, fever and time of survival At the same time an attempt was made to note the presence of changes in the blood-cell counts, of dermatitis and of other ill effects

EFFECT ON BACTEREMIA

In 5 of the 14 cases there was a definite drop in colony count on blood culture In the majority of cases four plates, each with 1 cc of blood, were poured, and the colonies counted and averaged An example of this fall in count is found in the following case

R. S. (No 183396), a 17-year-old girl, entered the Albert Merritt Billings Hospital September 11, 1937, on the service of Dr Allan T Kenyon. She was born a blue baby and lived against the expectation of the physician who delivered her About 2 years prior to admission she had had an episode of swollen and painful knee and ankle joints and spent 5 weeks in bed The onset of the present illness apparently occurred in April, 1937, when an acute upper respiratory infection was followed by pain in the lower chest posteriorly, not associated with respiration There was a weight loss of 35 pounds in the next 4 months Since April, 1937, there had been several attacks of epistaxis Profuse night sweats had been present for 1 month

On examination the patient was seen to be acutely ill The heart was enlarged to the left There was a thrill at the base and a loud diastolic and soft systolic murmur over this area At the apex was a blowing systolic murmur immediately following a markedly accentuated second sound A water-hammer pulse was present The red-cell count was 3,300,000, the hemoglobin 70 per cent and the white-cell count 10,400 A blood culture showed 117 colonies of *Streptococcus viridans* per cubic centimeter of blood Subsequent cultures showed 280 colonies on September 13, 129 on September 15 and 274 on September 17 On September 19, 44 gm (66 gr) of Prontylin was given, the dose being increased the next day to 48 gm (72 gr) daily By September 24 the colony count had fallen to 63 per cubic centimeter of blood and on September 28 to 39 On the latter day the Prontylin was stopped and the following note was made by the intern "No noticeable temperature change during Prontylin administration Hemoglobin remained about the same while Prontylin was being given." On October 5 the colonies numbered 32 On October 6 the patient developed nausea, vomiting and diarrhea, in spite of a blood transfusion and other supportive measures she died on October 15 Permission for an autopsy was refused

*In three of these diphtheroids were grown in the blood cultures and in the fourth a gram negative rod

A tabulation of the colony counts in 11 of the patients studied (Table 1) shows a definite fall

TABLE 1 *Effect of Sulfanilamide Therapy on Colony Count*

*Sulfanilamide was stopped for a short time after the second week the count rose to 32 but fell to 8 when sulfanilamide was resumed.

†The average dose of sulfanilamide in all but this case was 3 to 4 gm. (45 to 60 gr) daily, this patient received 6 gm (90 gr) daily

in count in 5 cases, a questionable change in 4 and a rise, in spite of sulfanilamide therapy, in 2

EFFECT ON FEVER

In the majority of patients with subacute bacterial endocarditis there is fluctuation in the height of the fever curve, it was therefore difficult to determine definitely whether the administration of sulfanilamide had any effect on the temperature In 1 case (Case 9), which is reported more fully below, a definite fall in the average level of the afternoon spike occurred two days after the drug had been started, the height of the spike was maintained at a nearly normal level for five days, for the next two months it was lower than it had been before sulfanilamide therapy had been started

TOXIC EFFECTS

Changes in White-Cell Count

In the majority of cases the white-cell count ran between 9000 and 14,000, with an increase in the percentage of polymorphonuclear cells In several cases the count fell to 600 during the course of sulfanilamide administration, but in all cases it rose immediately without specific treatment The fall was probably unrelated to sulfanilamide therapy, since this was also observed in cases not receiving the drug

Changes in Red-Cell Count

There were no cases of acute hemolytic anemia in this series There was, however, in most cases, a fall in the red-cell count, which probably occurred as a result of the disease process rather than because of sulfanilamide therapy In only 1 case was there a fall in the count that could be said to have

occurred immediately following the start of sulfanilamide therapy. The report follows:

R. F. (No. 200187) a 26-year-old woman was admitted on June 17 1938 on the service of Dr. C. Phillip Miller. She had had rheumatic fever at the age of 14. Following this illness she remained well until October 1937 when a tonsillectomy was performed. She bled severely following the operation and required four transfusions. Since the tonsillectomy she had been in bed becoming progressively weaker with the body weight decreasing from 150 to 92 pounds. During the first part of the illness she had pain under the costovertebral angles and considerable vomiting both of which had continued to the time of admission. In January 1938 she began to notice severe palpitation of the heart and joint pains in all extremities. Two weeks prior to admission her family physician had told her that she had an infection of the blood stream.

On physical examination at admission the patient was very weak and pale. The heart rate was 120 the heart was not enlarged there was a thrill at the cardiac apex, with systolic and diastolic murmurs over this area. The second pulmonic sound was accentuated over the aortic area could be heard a systolic murmur with a snapping second sound. The liver was felt 2 cm. below the right costal margin. The spleen was not definitely felt, but there was resistance on inspiration in the left upper quadrant of the abdomen. There was slight clubbing of the fingers. The red-cell count was 3,100,000 and the white-cell count 10,350. On June 18 a blood culture showed 129 colonies of *Streptococcus viridans* per cubic centimeter of blood. On June 19 sulfanilamide was started in doses ranging from 3.6 to 5.4 gm. (55 to 80 gr.) per day. The colony count on this day was 133. On June 20 the red-cell count was 4,200,000 the hemoglobin 54 per cent and the white-cell count 13,560. By June 24 the red-cell count had fallen to 2,800,000 and the hemoglobin to 42 per cent the white-cell count had risen to 20,000. Meantime the colony count had dropped to 5 per cubic centimeter of blood and on June 29 it fell to 4. On June 26 the patient was given a transfusion of 500 cc. of blood. The red-cell count ranged between 2,800,000 and 3,040,000 until July 2 when the drug was stopped because the patient complained of a severe headache. The headache was gone by July 4 and sulfanilamide was resumed. It was stopped on July 6 because of intense dizziness, and resumed on July 15. On August 2, however the drug was again stopped because of the appearance of papilledema without other eye signs or symptoms. On July 21 a fall in temperature from 102 to 100 F was noted, and the latter level persisted until August 11. On July 29 a blood culture grew an average of 2 colonies per cubic centimeter of blood. On August 6 the patient felt better. The red-cell count ranged from 3,140,000 on July 17 to 2,460,000 on August 4 and 3,950,000 on August 14. On August 11 sulfanilamide was again started on August 12 the patient began to have nausea after each dose. She developed a left hemiplegia and facial paralysis on August 14 gradually failed, and died on August 23.

The autopsy findings included subacute bacterial endocarditis affecting the mitral valve and wall of the left atrium, antecedent chronic rheumatic mitral valvulitis and left atrial endocarditis, moderate mitral stenosis and rheumatic aortic endocarditis, minimal and healed.

Comment. In addition to the mild hemolytic anemia noted between June 20 and June 24 the severe headache, nausea and papilledema were all believed to have resulted from the toxic action of sulfanilamide.

Dermatitis

One patient developed a dermatitis which was thought to have resulted from sensitization of the skin to sunlight by sulfanilamide. The report follows.

C. E. (No. 219952) a 28-year-old man was admitted May 7 1939 on the service of Dr. George F. Dick. He complained of weakness, fatigue and fever of 8 months duration and sore fingers of 3 months duration. For the last 3 months he had developed ankle swelling and tiny red areas on his feet and ankles after standing for 15 to 30 minutes. He had had rheumatic fever each winter from the age of 12 to that of 18. Prior to the time of onset of the present illness he had worked as a railroad clerk and had felt well.

On physical examination the patient was pale there were petechiae over the left scapula and over the left tibia in its middle third. The posterior pharynx was red and granular the tonsils had been removed. Over the lung bases were increased breath sounds with subcrepitant rales which cleared on coughing. The heart rate was 120 the apex by palpation was 10 cm. to the left of the midline in the fifth intercostal space. There was a systolic thrill at the apex with a systolic apical murmur referred especially to the left axilla but audible over the entire precordium. The right testis was undescended. There was puffiness but no pitting of the feet and ankles. A tender, red area 1 cm. in diameter was noted on the left index finger. The red-cell count was 3,100,000 and the white-cell count 9000. A blood culture was positive for *Streptococcus viridans* with 40 colonies per cubic centimeter. On May 13 the administration of sulfanilamide was begun. The oral temperature up to this time had been rising daily to around 102 F at 4 p.m. By May 15 the curve had flattened and until May 20 the rectal temperature did not rise above 99 F. From May 20 to July 20 it reached a daily peak of 102 F. On May 21 because of a rise in the pulse to over 140 the patient was digitalized and received from 0.1 to 0.3 gm. (1 to 3 cat units) of digitalis daily thereafter. On May 29 the colony count was 40 per cubic centimeter of blood and on June 9 20.

On May 31 after 18 days of sulfanilamide therapy the patient developed a macular erythematous rash, blanching on pressure, over the left side of the body. This was thought to be a dermatitis medicamentosa, and members of the Dermatology Service concurred in this diagnosis. At the time of appearance of the rash the patient had been receiving 3.6 gm. (54 gr.) of sulfanilamide daily which had kept the blood level at about 13.3 mg. per 100 cc. 0.6 gm. (10 gr.) of ferrous sulfate daily 0.2 to 0.3 gm. (2 to 3 cat units) of digitalis daily 0.010 gm. (1/4 gr.) of morphine sulfate four times a day and nasal oxygen. The patient's bed was so situated that the sun shone on the left side of his body from 1 p.m. until evening each day and it was the opinion of the attending physician and members of the Dermatology Service that sulfanilamide sensitization to sunlight was the most probable etiologic factor.

On July 20 the patient began to have hiccoughs, a rise in rectal temperature to 102.6 F increased rales in both lung bases and a rise in pulse to 140. In spite of blood transfusions and general treatment, he died on July 29.

The autopsy findings included subacute bacterial endocarditis, embolization of small vessels throughout the body mesenteric embolus with peritonitis, and early bronchopneumonia.

EFFECT ON TIME OF SURVIVAL

Of the 76 cases of subacute bacterial endocarditis which have been seen at the University of Chicago Clinics since 1930, it was possible to determine the date of death in 40. In 10 of these the patients had received sulfanilamide. All had been found to have a bacteremia caused by *Streptococcus viridans*. The date of onset was not easily determined. In many cases it was based on a his-

longer than seven months, none lived longer than eleven months. In the group of 30 patients treated without sulfanilamide, the time of survival ranged from two to seventeen months, the average being 5.6 months. Five patients lived longer than seven months and 3 longer than eleven months. Certainly, on the basis of these statistics, no effect on the prolongation of life by sulfanil-

tory of influenza or similar acute upper-respiratory infection in a previously symptomless individual, followed by chills, fever, cardiac signs, weight loss, weakness and embolic phenomena. Occasionally it was calculated from the date of surgical procedures which were followed by the symptoms just noted. Table 2 summarizes the cases studied.

The 10 patients who received sulfanilamide, averaging about 3 gm (45 gr) daily, lived from one to eleven months after onset. The average time of survival was 5.6 months. Three patients lived longer than seven months, none lived longer than eleven months. In the group of 30 patients treated without sulfanilamide, the time of survival ranged from two to seventeen months, the average being 5.6 months. Five patients lived longer than seven months and 3 longer than eleven months. Certainly, on the basis of these statistics, no effect on the prolongation of life by sulfanilamide can be observed. The average length of life after onset in each of the two groups was the same, while the fact that 3 untreated patients lived longer than eleven months, and that none of those treated did so, might be interpreted as indicating that sulfanilamide actually shortened the time of survival.

SUMMARY

Sulfanilamide therapy had no effect on the general course of 13 cases of subacute bacterial endocarditis.

The main beneficial effect was a fall in the number of bacteria in the blood stream

In one case there was a definite drop in the temperature curve coincident with the use of sulfanil

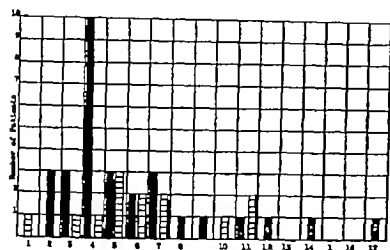

FIGURE 1 Length of Life (After Onset) of Patients with Subacute Bacterial Endocarditis

The cross-hatched blocks represent patients who received sulfanilamide the solid blocks those who did not

amide, in other cases it was thought possible that lowering of the level was related to use of the drug

In general no severe toxic effects were noted. At least one case of hemolytic anemia was noted. There was one case of dermatitis believed due to sensitization of the skin to sunlight by sulfanilamide. Nausea, headache and papilledema were

also noted, and were believed to have been caused by the drug

Sulfanilamide did not prolong the life of patients in this series, and there is some evidence that it may have actually shortened the time of survival.

SODIUM MORRHUATE IN THE TREATMENT OF EPICONDYLITIS OF THE HUMERUS

A Report of Five Cases

FRANK A. SLOWICK, M.D.*

PITTSFIELD, MASSACHUSETTS

RECENT unsatisfactory results in the treatment of epicondylitis of the humerus, or radiohumeral bursitis, by conservative methods, have led to a search for a simple nonsurgical method which would give greater promise of relief and cure. Experience with conservative treatment by physiotherapeutic and other means has resulted only in the discouragement of physician and patient. In 1937, while considering the efficacy of sodium morrhuate obliteration of prepatellar bursas, I decided to use the drug in a case of epicondylitis which was very resistant to the usual physiotherapeutic methods. The successful cure of this case after two injections of sodium morrhuate, and the complete freedom from all symptoms in two

months, led to the further application of the method

A search of the literature on this subject reveals that there are many divergent opinions regarding pathology and treatment. The review of North¹ is all that can be desired for an understanding of the various phases of the subject. Of interest is Cynax's² view that injections by alcohol, carbolic acid and novocain are uncertain are of small significance and have little effect on the course of disability. He is of the same opinion regarding rest, x-ray therapy, diathermy, ionization and removal of foci of infection.

While only passing mention is made of novocain infiltration in the American literature the French have taken this method of treating the

*Consulting orthopedic surgeon, House of Mercy Hospital, Pittsfield, orthopedic surgeon, St. Luke Hospital, Pittsfield.

condition more seriously Massart³ in 1935 reported the cure of three tennis players by the injection of novocain into the painful region. He endorsed the method for its satisfactory results, and credited Leriche with its application in this condition. Leriche⁴ confirmed the efficacy of the method and stated that he tried it first in 1928 and obtained a cure with two injections. Tavernier⁵ questioned these results and stated that in his hands the method was not so regularly efficacious as Massart believed. It is my own opinion that the infiltration method has been passed over too lightly. Its very simplicity has taken away from the method the serious consideration it deserves.

The first three cases reported here are from my own experience. The last two cases are from the records of my brother, Dr. Joseph E. Slowick, of Palmer, Massachusetts, who was induced to try the method on my recommendation.

CASE REPORTS

CASE 1 W D G, a 38-year-old automobile service-station manager, was first seen on May 22, 1937. He complained of pain on the outer surface of the left elbow on movement. He stated that 4 days previously, while changing a tire, he had turned and struck the handle of the jack with his left elbow on the bony prominence of the outer surface. From that time he complained of pain on motion of the hand. The arm tired easily, and at rest there was a feeling of numbness. He had never had trouble with the elbow before.

Physical examination showed a young man of rugged physique. The examination was not remarkable. The teeth were negative on gross examination. The tonsils had been removed. The left elbow, as compared with the right, showed a slight fullness just distal to the epicondyle, which was tender on pressure in an area about 0.9 cm in diameter. Grasping and flexion and extension movements of the hand caused pain at the injured area. There was no discoloration. X-ray examination of the elbow on May 22 showed no bony changes.

A diagnosis of epicondylitis was made and treatment by diathermy and massage was started, and was continued until July 3, three times weekly. There was no improvement at the end of that time. This treatment was discontinued and 0.5 cc of 1 per cent novocain was injected into the site under the tendon of the extensor group. There was immediate relief by this procedure, with recurrence the next day.

Five days later a second injection of novocain was made, with the same result. On July 13 the skin and subjacent tissues were injected with a small amount of novocain, and 0.3 cc of 5 per cent sodium morrhuate was injected into the area under the extensor tendon. On July 16 the patient reported that in the interim there was an exaggeration of symptoms, but on that day the flare-up had subsided. At subsequent visits on July 19 and 25 and August 3 there was a definite diminution of the pain on movement of the wrist and hand. A second injection of 5 per cent sodium morrhuate was made on August 4.

On August 20 the patient reported that a slight flare-up had again occurred, which lasted 3 days. Following this

there was a rapid disappearance of the pain. On September 2 he was completely well. Following the first injection of sodium morrhuate there was an increase in the swelling at the site, and there was a slight fluctuation in that area which continued until the last visit on September 2.

On June 14, 1939, the patient reported that he had been entirely well since the visit of September, 1937. An x-ray examination at this time revealed no bony changes at the site of the external epicondyle.

CASE 2 A M, a 41-year-old woman, was seen on October 15, 1938. She was employed as an imprinter, operating a machine which required her to move the hands and arms from side to side, and toward the midline of the body. She had been doing this work for several years. Three months before this examination she began to complain of pain over the external aspect of the right elbow. The joint seemed stiff and painful on using the arm and hand in her work. With a rest over a week the condition improved, but when she resumed her work the soreness at the elbow returned. Six years previously the patient had been in an automobile accident and sustained a severe bruise over the external condyle of the right humerus in the region of the present painful area. She had always felt a sensitiveness in that region, but never the present soreness and stiffness. Her appendix was removed 5 months previous to examination. She had had scarlet fever seven years previously.

Physical examination was not remarkable. The right elbow showed a slight fullness just distal to the external epicondyle, which was tender on pressure. Pronation of the forearm and flexion of the wrist with the elbow extended caused pain. Dorsiflexion of the wrist also caused pain in that region. Passive extension of the elbow was complete, but a definite spring was felt when full extension was approached. There was no other tenderness about the elbow. X-ray examination of the elbow on October 15, 1938, showed no alterations of the bony structures and no unusual soft-tissue shadows.

A diagnosis of epicondylitis of the right humerus was made, and treatment with sodium morrhuate was offered and accepted. The first injection was given on October 18, 1938. First, 0.5 cc. of 1 per cent novocain was injected into the tissues beneath the extensor tendon. Then 0.3 cc. of 5 per cent sodium morrhuate was injected beneath the tendon at the attachment. The pain was temporarily aggravated beginning the next day, but subsided in the next 2 days to a dull ache. On October 22 there was found at the site an area of tenderness, with fluctuation over the tendon of the extensor group just distal to the epicondyle.

The patient had been advised to change her work for a short period, and obtained a transfer to clerical work. She was able to continue this throughout the course of her treatment.

On October 25 the treatment was repeated. On November 5 the patient reported that the condition was again aggravated by the sodium morrhuate, but that within 2 days it had subsided markedly. Thereafter there remained only a dull ache. On November 22 she was again examined. There was no complaint on this visit, and the ache had disappeared. There was still a sense of fullness and fluctuation over the epicondyle and attached tendon.

On December 17, the patient reappeared for a checkup and reported that she was well. There was no tenderness, although there was slight fullness in the region of the extensor tendon. On July 19, 1939, she reported that she

had been completely well since the visit of December 1938. She had resumed her usual work.

CASE 3. L. S. C. a 35-year-old woman was first seen on July 11 1939. She complained of pain in the right elbow. She stated that 2 months before, while playing with her son she struck her right elbow thereafter there developed a painful condition at the site of the injury and while she was able to drive a car and do housework, it had continually troubled her. She was unable to grasp pull threads or shake down a thermometer. She obtained temporary relief by hot soaks. Fully extending the elbow aggravated the pain. She had been well previous to the onset of this condition.

At physical examination the right elbow showed a tender area over the external epicondyle, and there was pain on pronating the forearm and flexing the wrist. Extension of the elbow produced a slight spasm when the extreme of the movement was approached, and on such motion the patient complained of pain at the external epicondyle of the humerus. A diagnosis of radiohumeral bursitis was made and the injection treatment was offered and finally accepted.

The first treatment was given on July 24 when a small amount of 1 per cent novocain was injected, followed by 0.3 cc. of 5 per cent sodium morrhuate. On the next day the patient reported that there was a marked increase of pain on moving the hand and wrist. She was unable to fully extend the elbow because of pain. There was slight redness and swelling above the site of the injection. On July 27 she reported improvement but the elbow still felt sore. On August 5 there was no pain whatever. There remained only a slight stiffness in the movement of flexion. The range of motion was normal. There was still present an area of fluctuation distal to the epicondyle, but there was no tenderness. On that day a second injection of 0.3 cc. was made, following a small amount of 1 per cent novocain. On August 12, the patient stated that she had had no pain, but that there was a mild reaction on the day following the injection. Early each morning she noted a dull ache at the epicondylar area. All movements of the elbow and forearm were normal and painless. Examination showed a slight amount of fluctuation still present at the site of injury. On September 9 she stated that she had had no pain since the previous visit, and there was no tenderness on pressure over the area. The motions were normal. She was discharged.

CASE 4. A. W. J., a 48-year-old man was seen on November 1 1938. He complained of pain at the outer aspect of the right elbow. On October 20 he had struck the elbow on a store counter. Pain occurred and increased and there was inability to grip and to supinate forcefully the forearm and hand. Otherwise the patient had been well and worked long hours as a store proprietor.

Physical examination showed a well-developed and well-nourished man of medium build. There was marked tenderness over the external epicondyle of the right humerus, with pain in that region on forceful extension of the wrist and supination of the forearm and hand. X-ray examination revealed no bony changes in that region and a diagnosis of radiohumeral bursitis was made.

Treatment by conservative methods, including sedatives, diathermy and massage three times weekly until November 26, was carried out with only slight relief. Consequently on that day 0.3 cc. of sodium morrhuate was injected into the subcutaneous area at the insertion into the external epicondyle. On December 3 the patient reported considerable improvement. He could then grip

with the right hand. There was slight tenderness over the extensor attachment. A second injection was made on that date. On December 10 he reported improvement of the grip but still had discomfort at the extensor site. A third injection of 0.3 cc. of 5 per cent sodium morrhuate was made. On December 17 the patient reported only slight tenderness at the epicondylar area. His grip was good. On December 24 re-examination showed an excellent grip and only slight tenderness over the epicondyle. There was no pain on movement of the elbow or hand. On June 8 1939 the patient reported that he had been well since the visit of December 24.

CASE 5. J. F. S., a 44-year-old man was seen on February 2 1939. He stated that 4 weeks previously there developed pain in both elbows the right was quite sore, but the left showed less discomfort. There was no injury or strain that he could recall. He worked as an automobile service station manager. He had had pneumonia in childhood and influenza in 1918.

Physical examination showed a well-developed and well-nourished man. The temperature was normal. The tongue was slightly coated and the throat was congested. There were large infected stubs of tonsillar tissue in both fossae. The heart and lungs were normal. The elbows showed tenderness on pressure over both extensor tendons at the epicondyles, more marked on the right. There was no swelling. There was pain at the right elbow when attempting to grip.

Following the injection of 0.5 cc. of 1 per cent novocain 0.3 cc. of 5 per cent sodium morrhuate was injected into the subcutaneous area on the right side. On February 10 the patient reported aggravation of the pain and inability to extend the elbow fully for 3 days following injection. At this examination full extension was obtained. There was moderate tenderness in the region of the epicondyle. Another injection of 0.3 cc. of 5 per cent sodium morrhuate was made. On February 17 the patient reported a slight reaction the day after the injection, but for the next 4 days he had been well. Gripping with the right hand caused some pain in the region of the epicondyle. A third dose of sodium morrhuate was administered at this visit. On February 23 the area over the epicondyle was still painful. On March 7 the patient felt well. There was still slight tenderness over the right epicondyle. On March 20 he reported with a severe cold and remained under treatment for this condition until June 1 1939. On June 24 he returned and stated that there was only slight tenderness on pressure over the epicondyle.

SUMMARY

There has been presented an injection method of treating epicondylitis of the humerus, or radiohumeral bursitis, using sodium morrhuate as the sclerosing agent. The success of the method in a small number of cases warrants its further application. The number and frequency of treatments required must be determined by the application of the method in a larger number of cases. It is probable that slightly smaller doses may be used, thus minimizing the temporary reaction following each injection. The reaction in each of these cases was not so great as to prevent the patient from continuing his work.

The result in Case 5 while satisfactory was not

so spectacular as that in the other 4 cases. This would seem to indicate that the truly infectious type of radiohumeral bursitis does not respond so well as does the traumatic or noninfectious type. However, it does not appear to be contraindicated in cases which show foci of infection.

There has been no evidence of subcutaneous-tissue damage with the use of this sclerosing agent. While there is a theoretical possibility of injecting the sodium morrhuate into an extension of the joint capsule in that region, there has been no evidence of that complication following eleven injections in the 5 cases reported. It goes without

saying that the solution must be placed accurately and by one who understands the anatomy of the region.

SOME OPPORTUNITIES OF THE MEDICAL PROFESSION*

JAMES B. WOODMAN, M.D.

FRANKLIN, NEW HAMPSHIRE

IT IS a deeply appreciated opportunity to be here tonight because every meeting of this kind is just one more link in the chain of co-operation that we are trying to build up among all the factors of our great medical fraternity. Were I to be granted a single wish in rising to address this assembly, it would be that you, my esteemed associates, would be as impressed today as I have been impressed throughout the past year by the tremendous responsibilities placed upon us. We are servants of humanity and have a humanitarian service to perform which can be best accomplished by organization, co-operation and education.

These meetings serve many excellent purposes. They provide the opportunity for renewal of friendships, for interchange of ideas, for the taking of inventories of those abstract possessions which can be neither bought nor sold. Our task today is to achieve perspective, for we are told, "The young have aspirations that never come to pass, the old have recollections of things that never happened."

Within a little more than three hundred years the land which we call the United States has become the home of the fourth largest national group in the world. China, of course, is first, India, second, and Soviet Russia, third. When the United States was founded, republics were few and weak, and Europe predicted a speedy end of the young nation. For a time the future did seem uncertain, but dangers were overcome until now, in ex-

tent, stability, population, wealth and power, our republic ranks either first or among the first of the nations of the earth. May we realize this with humility and send up a prayer for the deliverance of our European brethren from their Gethsemane.

Daniel Webster said, "America has proved that it is practicable to elevate the mass of mankind,—the laboring or lower class,—to raise them to self-respect, to make them competent to act a part in the great right and the great duty of self-government, and she has proved that this may be done by education and the diffusion of knowledge." May we strive to maintain our self-respect and our personal as well as our national independence so that this high ideal may not be destroyed.

Opportunity is a word which, like so many others that are excellent, came from the Romans. It means "near port, close to haven." It is "a favorable occasion, time or place for learning or saying or doing a thing." It is an invitation to seek means for improving our efficiency and our service to our fellows. May we now ask what are some of the opportunities in the medical profession?

In the first place, the medical profession has the opportunity of furnishing an example of good citizenship. A good citizen is a man or woman who is doing something of service to the community. A good citizen is a workman who "needeth not to be ashamed." There is no fitting place in society for the selfish and the greedy, and we shall see in time that only insofar as the range and circle of our duties may include others and help and bless them, shall we find the true joy of living.

*Presidential address delivered at the annual banquet of the New Hampshire Medical Society, Manchester, May 15, 1940.

Secondly, the medical profession has the opportunity of safeguarding the health of the community and the State. The medical profession has done more for the race than has ever before been accomplished by any other body of men, insofar as general welfare is concerned. These gifts to the people have come in the form of vaccination, sanitation, anesthesia, aseptic surgery, bacteriology therapeutics and many other branches of medicine. For devoted service, for the highest expression of generosity and good will, the physician occupies a place quite incomparable. The story told by Ian Maclaren, in *Beside the Bonnie Brier Bush* of old Dr McLeod is not exaggerated or overdrawn. It is a tale that may be duplicated in any community. One must believe concerning men of this type that they are motivated by the highest of impulses, and that they minister under the Master, who never turned away from those who were bruised and broken in body. Like a team of two horses slowly pulling a heavy load out of the mire, the family physician and the specialist are, side by side, slowly but surely liberating the human race from the depths of disease. Their combined value cannot be measured in dollars and cents but rather in years of additional life. Together they constitute a great team.

Thirdly, the medical profession has an opportunity of setting an example of sympathy, charity and kindness. In each generation some of the best minds have devoted themselves to the study of the healing art. This will always be so. There is an allure to the practice of medicine which keeps the conscientious physician struggling on for his patient in the face of any difficulty. I like to believe that it is an inherent love of human kind, which makes life's ultimate goal the universal brotherhood of man.

Finally, the medical profession has the opportunity of an interesting future. With the greater knowledge of the causes of disease which time will bring us, there will be put into the hands of the physician of the future a weapon far more powerful than any we can wield today. We may reasonably look forward to the time when many of the evils which afflict us now will be avoidable, and as a result the span of the life of man which even in our own time has extended beyond what it was a hundred years ago, will be stretched far beyond the three score and ten that at one time were allotted.

The practice of medicine had its origin in the far distant past. Primitive man, the ancient ancestor of the present generation, was a savage

who named the earth, ignorant of the phenomena of his existence and of his surroundings. Fear of death was uppermost in his mind. He feared his fellow man and the wild beasts that inhabited the mighty forests, and fled in terror from such natural phenomena as thunder and lightning. He attributed all his misfortunes, including disease, to evil spirits that in his imagination peopled the air about him. To protect himself from these vile spirits he invented good spirits, charms and mystic rites. In due time some one member of the clan or tribe appeared to be more successful than others in combating these evil influences. This man became the magician or medicine man. He was the progenitor of the physician.

About four hundred years before the birth of Christ there lived in Greece a physician whose name was Hippocrates. He became the greatest physician of his age. He was the first to recognize the error of mysticism, magic and religion in medicine. He taught that disease was cured by the natural powers of the body. He practiced bedside observation of symptoms, examined the secretions of the body and investigated the digestibility of various foods. He established the practice of medicine on a rational basis. He also composed a code of ethics to govern the conduct of physicians. He declared that the true physician must be a man of honor, true to himself and honorable in his dealing with all men. This ancient code is the basis for the code of ethics that is in use today by the medical profession. In this day of many codes we of the medical profession can point with pride to this ancient code of ours that has been a lamp to guide the members of our profession throughout all the centuries of the past.

Gradually the science of medicine progressed until today we find not a finished product but a system that has reduced the incidence of disease to a point that is nothing short of miraculous. The death rate from disease has dropped to 9.6 per 1000 and nearly twenty years have been added to man's age expectancy. The number of newborn infants that may reasonably expect to reach maturity has been vastly increased. Trench after trench of man's great enemy, disease, has been taken in our war on that dread enemy of the human race. There remains much more to be done before disease will be entirely under control.

During all these centuries past the physician has never faltered in his endeavor to serve suffering humanity.

Perhaps the most puzzling question a physician ever asks himself is this, What do people expect from a doctor? And that probably suggests another, How do they make their choice when they decide to call a doctor? The great majority of physicians have confessed an inability to get unqualified and uncolored answers to these questions.

The principal reasons for the selection of a particular physician may be attributed to ability and personality: the former consists of economy, willingness, reliability, honesty and quickness, the latter of confidence, warmth of heart and sympathy. Universally, there is a desire to find a doctor in whom perfect trust can be placed.

The personal side of the practice of medicine, which has always played an important and comforting part, steps in at such times and renders a service which the people not only desire but demand. Sympathy, kindness, pity and cheerful hope—no amount of scientific efficiency can take the place of these in the dark hours of sorrow and trouble so common in the experience of all. President Eliot, of Harvard University, once said, "In these intangible things are found the durable satisfactions of life, fame dies and honors perish, but loving kindness is immortal." I should not belittle the importance of science in medicine,—I bow in humble reverence before its beneficent power,—nor should I magnify the personal element, yet many of us know from experience what comfort, hope and assurance the personality of a trusted physician may bring to the bedside of his patient.

At one time parent was parent and child was child. Whether six or sixteen or even twenty-six, the relationship and cleavage between the two was a marked and positive one. Never might the young one infringe on the territory of his parent or question his authority or wisdom. Now this has all changed. Parent is still parent and child is still child, but the old relationship exists in mere skeleton. But in spite of this there is no gainsaying that the wise parent, the cultured and educated and intelligent parent, still owes the same responsible and well-directed guiding spirit and hand to his family. Understanding, subtlety and common sense now enter into the picture. The parent who is not understanding, is not subtle in his direction and does not use the utmost common sense will today fail in his task.

As the modern parent, so the modern physician. The young physician usually bears all the eagerness, all the restlessness, all the liberalism, all the anxious tempo of quick accomplishment. His virtue is his sincerity and his enthusiasm, but his

handicap is inexperience. Who then is in a better position to temper the mood of the young, if not the informed older physician? With patience and tolerance borne of long acquaintance with every type of patient, with knowledge borne of many trying events, with experience in every type of case, hospital, scientific study and probable danger, he is in a position to be of lasting benefit to his junior. As the parent, so the senior physician can shape and guide and build and create so that the result in the young physician, grown to maturity, will be one of young scientific knowledge, tempered by old wise experience.

But let him be careful not to use the parental methods of half a century ago. Let him avoid the pitfall of brash and crass wordage, that I-am-older-than-you-and-therefore-know-and-say attitude which will bring him certain defeat. Let the senior physician be understanding. Let him remember his own youthful experiences, his youthful successes, his youthful defeats. Let him recall his own disillusionment at the lengths to which duty goes in calling upon the physician for public service and let him ever make it clear that it is never to be considered as a burden. Let him, through understanding, serve his junior physician and all mankind.

Let the senior physician be subtle. A scientific attitude requires open-mindedness and tolerance of large measure. Only through subtlety will this attitude be continually cultivated to greater and greater heights until it reaches the pinnacle of true service. So much more will be accomplished through the gentleness of subtlety than through the harshness of hard and cold untempered fact.

Let the senior physician feel called on more than ever to exercise his common sense. Let him realize he must not look back but ahead. He must not think in terms solely of the past. He must look to the future, knowing that the young physician will one day supersede him. Let him prepare for that day by revealing no weakness of personal character in learning from the junior, all the while he is teaching the latter the craft of the senior. Let him tax his reason to yield ever to the exigencies of the moment.

All these traits bear manifold relations to patient and physician, to student and practitioner.

Since we have had organized medicine we have made more progress and the science of medicine has reached a higher plane than was possible had each one continued in his isolated and selfish life. It is my belief that we are outstripping all other professions in progress and development today.

We are ever looking forward and blazing the trail for others

The benefits given by the medical profession to the general welfare are but little understood and less appreciated. Where would we be today if medical science had done nothing toward the control of smallpox, diphtheria, typhoid fever and malaria? What would happen if the doctors went on a sit-down strike for ten years?

If the following achievements are realized by the medical profession the life span will be lengthened still further the further control and mastery of the remaining infectious diseases an understanding of the factors that produce diseases of the heart and blood vessels, and the solving of the mystery of cancer and its cure. It is not an unfounded hope that makes me believe that these conquests will be realized some day. By the actual progress of investigations in physics, chemistry and biology now under way the problems presented by these great outstanding menaces to mankind are already partly solved. Their further solution depends on the continuance of scientific work, together with public education.

But let us be alert. Let us beware of pitfalls. There are wolves in sheep's clothing who would have us import some European system of medical care, with its paternalism, its regulation and its regimentation of both physicians and public, which, to my mind, are not in accordance with the American way of life. While dangling in plain view the bait of free medical service they hide the concomitant necessity of compulsory sickness insurance out of the poor man's pay envelope, to cover not only the cost of medical care but the added expense of another bureau

of regulators which would approximate if not exceed the Post Office Department in size and expense of personnel.

May we escape further centralization of power in this free nation? Propaganda in favor of taking the practice of medicine out of the hands of physicians and turning it over to be controlled by the politicians has been vociferous and without ceasing. A steady barrage of newspaper items, magazine articles, radio addresses and speeches has been aimed at the medical profession by these proponents of state medicine, with the obvious intention of breaking down the confidence of our patients in our trustworthiness.

Have we ever played into the hands of these gentlemen by what may have appeared to the patient and his family to have been a lack of sympathy, callousness or perchance, the highly mercenary attitude? I wonder.

But I am talking too long. With this word I come to my conclusion. You remember that old custom of the monks of Aberdale. When they came to a house and asked for alms or food or shelter, if it was denied to them they were wont to raise their hands with cursing gesture and their voice in *Maledicite maledicite*. But if they received their dole, the gesture was reversed and in their softest tones they spoke their gratitude in *Benedicite benedicite*. Thus, it must be those who do know you who judge you wrongly and howl maledictions. I who have known you, who have felt of your favor who have been warmed by your kindness—I who have gained a new respect for your power and an even greater confidence in your gentleness—I pronounce my humble but, believe me my heart felt, *Benedicite benedicite*.

REPORT ON MEDICAL PROGRESS

ELECTROCARDIOGRAPHY IN GENERAL MEDICINE*

LAURENCE B. ELLIS, M.D.†

BOSTON

WITH the increasing availability of the electrocardiograph, every physician, general practitioner and specialist alike has occasion in these times to utilize this laboratory aid to cardiac diagnosis. One cannot hope to be truly adept at electrocardiographic interpretation without a considerable amount of study and experience, but every doctor should be able to answer these questions, What information will the electrocardiogram furnish, and what are its limitations? He should know when to demand an electrocardiogram in order to obtain vital information regarding his patient, and when a tracing is unnecessary or useless.

This article will endeavor to answer these questions. No attempt will be made to provide a résumé of electrocardiographic interpretation, there are several excellent texts which cover the subject adequately. Certain of the recent advances in electrocardiographic interpretation will, however, be mentioned.

With the development in 1903 of the delicate string galvanometer by the physiologist Einthoven, of Leyden, a new weapon was added to the armamentarium of those interested in the diagnosis and treatment of heart disease. Originally introduced as a laboratory aid in the study of the physiology of the heart, the electrocardiograph was quickly taken up by cardiologists, and soon became almost the hallmark of their special craft. In recent years, however, internists and general practitioners have to an increasing extent added it to their laboratory equipment. Although the bounds of its usefulness have, no doubt, not yet been fully explored, its value and its limitations are now fairly clearly defined, and at the present time the danger is not so much that electrocardiographic abnormalities will be missed by physicians not highly experienced in electrocardiographic interpretation, as that they will seek to use it beyond its limitations as an all-seeing eye for cardiac diagnosis, and will fail to correlate electrocardiographic

findings properly with the clinical state of their patients.

The basic principle of the electrocardiogram is simple. Whenever a cell is activated, be it one which conveys a nerve impulse or a muscle cell which contracts, a difference in electrical potential is set up between the activated portion of the cell and the resting part, which can be detected by placing electrodes on the cell and registering the electrical changes by a sufficiently delicate galvanometer. Where a great number of such cells are involved, as in the heart as a whole, the record which is obtained is a summation of these electrical stresses registering in succession the phases of the cardiac cycle. The magnitude of the changes is a measure of the degree of unbalance of the stresses, and is not a measure of the mechanical force of the heart beat. Indeed, the point at which the heart is contracting most forcibly, that is, the peak of ventricular systole, may coincide with a point on the electrocardiogram where there is no deflection whatsoever. It is obvious, therefore, that only those conditions within the heart that produce electrical changes will be registered on the electrocardiogram, hence its usefulness will be limited within these bounds.

The type of electrocardiographic machine based on the string galvanometer introduced by Einthoven is still in use, but in addition the oscillographic type of machine, depending on the amplification of the minute electrical current by vacuum tubes, is now also very widely employed. A source of light conveys the image of the moving string or of the galvanometer mirror, to be registered on a moving photographic film. In addition, a time marker is usually introduced, so that there is direct photographic registration of time intervals of 0.04 and 0.20 second. Horizontal bands on the film permit the standardization of the record for each patient, so that a deflection of the string of 1.0 cm. is equivalent to 1.0 millivolt.

In taking electrocardiograms in clinical practice the electrodes are placed on certain arbitrarily chosen portions of the body with the heart lying between them, the body thus acting as a passive

*From the Thorndike Memorial Laboratory and the Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine Harvard Medical School.
†Associate in medicine, Harvard Medical School assistant physician Thorndike Memorial Laboratory Boston City Hospital

conductor In order to obtain the maximum recording of electrical changes taking place in different directions, three successive arrangements of electrodes or leads are taken, labeled Leads 1, 2 and 3, and known as the standard leads Lead 1 is obtained by connecting an electrode placed on the right arm to one on the left arm Lead 2 extends from the right arm to the left leg, and Lead 3 extends from the left arm to the left leg A triangle is thus formed enclosing the heart in three directions Since the electrical axis of the heart normally lies nearly parallel with the axis of Lead 2, the various waves of the electrocardiogram tend to be higher in this lead than in Lead 1 or 3

It will be noted that although the axes of the three standard leads cut the heart in different directions, they all lie in the frontal plane. Now, the heart being a three-dimensional organ it must often happen that disturbances occur within it which would be registered only by electrodes placed along an anteroposterior axis It would seem offhand that electrodes so placed that one was situated on the chest in the precordial area and the second directly behind it on the back would register this axis as desired. This is not exactly the case, however, because of the position of the heart in essential apposition to the anterior chest wall, while separated from the back by a comparatively thick layer of rather poorly conducting lung tissue. Since the registration of electrical disturbances is in inverse proportion to the distance from the electrode, it is obvious that the electrical changes produced in the neighborhood of that portion of the heart lying beneath the anterior electrode will dominate in producing the resultant electrocardiographic pattern The chest leads therefore tend much more to localize than they do to depict the general composite pattern of the electrical changes occurring throughout the heart

Chest leads have come into general use in clinical electrocardiography since the demonstration in 1932 by Wolfarth and Wood¹ of their value in the diagnosis of fresh cardiac infarction Since they are especially useful in detecting focal lesions they are of particular help in revealing this condition, but their value is by no means limited to this state, and it is now the general practice to include a chest lead (Lead 4) in every electrocardiographic tracing

As study of the technic of the chest lead progressed, it was soon found that a part of the body such as a leg or an arm would serve as well

as the back for the indifferent electrode, and therefore, for the sake of convenience, the left leg or the right arm is now generally employed The chest electrode is usually placed over the apex of the heart and the resulting leads are labeled Lead 4F or Lead 4R, depending on whether the left leg or the right arm is used for the indifferent electrode Occasionally other precordial leads are utilized Standard criteria for the taking and naming of these chest leads have recently been established by a joint committee of the American Heart Association and the Cardiac Society of Great Britain and Ireland²

THE NORMAL ELECTROCARDIOGRAM

In order to understand what the electrocardiograph is capable of doing and what one should not ask of it, a brief description of the normal electrocardiogram is necessary This consists of several component parts, representing the successive phases of the cardiac cycle Each wave or

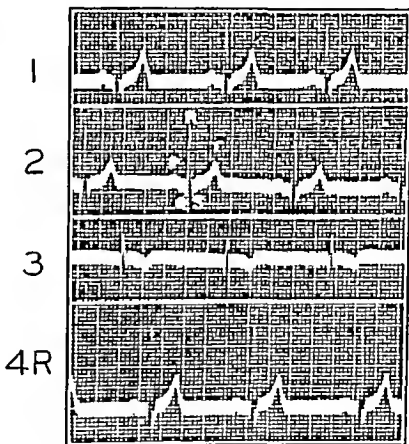

FIGURE 1 Normal Electrocardiogram

Slight sinus arrhythmia rate approximately 60 P waves upright in Leads 1, 2 and 4 not visible in Lead 3 PR interval = 0.14 second QRS interval = 0.09 second T waves upright in Leads 1, 2 and 4 inverted in Lead 3 axis normal

deflection from the isoelectric base line signifies a change in electrical potential produced by the spread of an impulse of excitation or the contraction of the cardiac muscle. To these successive waves the letters P, Q, R, S and T are applied (Fig 1)

The initial deflection, the P wave, is produced

by the spread of the wave of excitation from its origin in the sinoauricular node through the auricles and the contraction of these chambers. It is normally upright, in Leads 1 and 2 at least, and of small amplitude and short duration, and frequently is invisible in Lead 4 and even in one or two of the standard leads. If it is absent in all leads, however, it indicates that the auricles are not beating, as, for example, in the case of auricular fibrillation.

The PR interval, or the time interval from the beginning of the P wave to the commencement of the QRS complex, gives a measure of the speed of conduction between the sinoauricular and auriculoventricular nodes, and is usually between 0.14 and 0.16 second, with an upper limit of normal of 0.20 second or somewhat less,³ depending on the age and size of the patient and the heart rate. When the PR interval exceeds the normal, partial heart block is present, this may be due to abnormal vagal stimulation, toxic damage or disease of the conducting mechanism. If greater interference with the conducting mechanism occurs, certain of the auricular impulses may be completely prevented from reaching the ventricles, resulting in dropped beats or 2 1, 3 1, 4 1, or complete auriculoventricular heart block.

Ventricular activity commences with the QRS complex. The wave of excitation spreads from the auriculoventricular node down the bundle of His and its right and left branches and through its arborizations to the ventricular muscle. The mass of tissue in the bundle of His and its main branches is probably too small and the speed of conduction too rapid to be registered to any extent on the electrocardiogram. The QRS complex, mainly at least, represents the invasion of the muscle by the excitation waves. The R wave is always upright, if the initial deflection is downward this portion is called a Q wave and if a downward deflection follows the R wave it constitutes an S wave. Normally the predominant wave in all leads is the upright R wave, and the Q and S waves are small and frequently missing altogether. The contours of the waves of this complex are normally sharp, and the total duration does not exceed 0.10 second. When the QRS interval is longer than this, damage to the conducting mechanism, known as intraventricular block, has occurred, and when these abnormal waves have a characteristic pattern it can be inferred that the delay is mainly in either the left or the right bundle. The maximum amplitude of the Q, R and S waves in the standard leads, which in normal persons means the R wave, is higher than

either that of the P or the T wave, and is 0.5 millivolt or greater. If the maximum amplitude is less than this in all the standard leads, it suggests that myocardial disease is present, although in the absence of other electrocardiographic abnormalities it is unwise to diagnose heart disease from this sign alone. A certain percentage of normal persons show a minor degree of low voltage, possibly due to the position of the heart in the chest. Among other causes of low voltage in persons with normal hearts are pulmonary emphysema, generalized edema and effusions into the abdomen, chest and pericardium. Myxedema may produce such low amplitude, and a possible cause of finding low voltage erroneously is an improper standardization of the leads, especially in patients with high skin resistance (when the string-galvanometer type of machine is used).

When the S wave is more prominent than the R wave in Lead 3, the electrical axis of the heart, which very roughly corresponds to the anatomical axis, has been shifted to the left, or lies more nearly horizontally. If extracardiac causes for such a shift are excluded, the deviation usually represents a relative enlargement of the left ventricle, such as is seen in patients with hypertension or aortic regurgitation. If, on the contrary, the S wave is greater than the R wave in Lead 1, right-axis deviation is present, and is suggestive of relative right-sided cardiac enlargement, such as, for example, occurs with mitral stenosis or cor pulmonale.

The active phase of ventricular muscular contraction commences with the subsidence of the QRS deflections and is represented in the normal electrocardiogram by an isoelectric period, followed by a wave which is upright (except occasionally in Lead 3), the T wave. Ventricular systole ends and diastolic relaxation commences at or before the apex of the T wave. In pathologic states the normally isoelectric ST interval may be elevated above or depressed below the base line. Except when the QRS complex itself is markedly abnormal, or when there is a marked degree of axis deviation, significant degrees of such elevation and depression are usually associated with acute injury to the heart, and are mainly seen in patients with acute myocardial infarction or pericarditis.

The T wave, which normally has an amplitude of 0.1 to 0.5 millivolt, may become flattened or inverted under certain circumstances usually associated with toxic damage, ischemia or disease of the ventricular myocardium. Normally the T wave in Lead 3 is frequently flat or inverted.

The total duration of ventricular systole is roughly computed to the electrocardiogram from the QT interval, the normal limits of which vary with the heart rate and to some extent with the sex of the patient.⁴ This interval may be prolonged as the result of heart disease, but also may be lengthened as the result of toxic states, as in uremia, or through the effect of quinidine

VALUE OF THE ELECTROCARDIOGRAM

Bearing in mind what the electrocardiogram really is and what it registers, it will be of assistance in the diagnosis of pathologic cardiac conditions by demonstrating the following conditions

- I Disturbances of rhythm
- II Disturbances of conduction
 - (a) Between auricles and ventricles (auriculoventricular block of varying degree)
 - (b) Within the ventricles (intraventricular and bundle-branch block)
- III. Shift of the electrical axis of the electrocardiogram as the result of
 - (a) Relative enlargement of one or more chambers of the heart
 - (b) Displacement or rotation of the heart within the thoracic cavity
- IV Damage or disease of the myocardium as the result of
 - (a) Toxic damage or infection
 - (b) Coronary disease and myocardial ischemia
 - (1) Acute myocardial infarction
 - (2) Chronic coronary disease
 - (c) Acute pericarditis
 - (d) Pulmonary embolism

These will be considered in the following paragraphs.

Disturbances of Rhythm

Cardiac arrhythmias can usually be diagnosed by the electrocardiogram with a high degree of accuracy, and the polygraph has been almost entirely replaced in clinical use by the electrocardiograph for this purpose. Of course, many of the arrhythmias can easily be diagnosed at the bedside by palpation and auscultation, although one's adeptness at such bedside diagnosis is greatly enhanced by the check of an electrocardiogram. However, there are certain conditions which can be distinguished clinically with the greatest of difficulty or not at all, and they often carry very different indications for treatment. Thus it may be very hard to tell whether one is dealing with auricular fibrillation or numerous premature contractions, or even, on occasion, with sinus arrhythmia, and it is impossible clinically to judge whether extra

systoles arise from a single focus or multiple foci, although the latter are much more important. Paroxysmal auricular and ventricular tachycardia can be differentiated only by the electrocardiogram, and both are easily confused clinically with auricular flutter with 2:1 block, and with a rapid sinus tachycardia. Complete heart block and sinus bradycardia may be clinically indistinguishable, and high-grade partial heart block with a regular ventricular rhythm may be missed altogether clinically.

Disturbances of Conduction

Auriculoventricular block Partial heart block resulting merely in a prolonged auriculoventricular block conduction time can only be diagnosed by the electrocardiogram or the polygram. The greatest importance of this finding as a diagnostic sign is in connection with rheumatic fever. At least 30 per cent of all patients with active rheumatic infection show a prolonged PR interval at some time during the course of the disease. This occurs quite irrespective of whether or not endocardial lesions develop. Since this electrocardiographic sign is so common in rheumatic fever and so rare in other types of arthritis, it is frequently of great help in establishing a diagnosis of this disease, which is very often obscure in its manifestations. Moreover in those cases in which partial heart block is persistently present, the electrocardiogram furnishes a valuable guide as to the duration of activity.

Many other conditions can of course produce prolonged auriculoventricular conduction. Digitalis is perhaps the commonest cause, and the presence of partial heart block, together with other electrocardiographic signs of digitalis toxicity, may provide a helpful indication as to whether the patient has had too little or too much digitalis.

Any type of heart disease may produce transient or permanent partial block, provided the lesion is so situated as to interfere with auriculoventricular conduction. It is not, however, very commonly found as a permanent manifestation of chronic heart disease. It frequently does occur transiently in acute myocardial infarction of the posterior type, due usually to thrombosis of the right coronary artery. About 15 to 20 per cent of cases of posterior infarction show prolongation of the PR interval, and in about 3 per cent higher grades of heart block are present.⁵ Such prolongation may be the only electrocardiographic sign of cardiac infarction.

Higher grades of heart block ranging from dropped beats to complete block, are merely ac-

centuations of partial heart block of the type discussed above and are due to precisely the same causes

Intraventricular and bundle-branch block Intraventricular and bundle-branch block can only be diagnosed with certainty by the electrocardiogram. The terminology and exact electrocardiographic diagnostic criteria for the various types of bundle-branch block have undergone a good deal of modification during the past few years. It is probably wisest at the present time to adopt the criteria laid down by the New York Heart Association.⁶

Bundle-branch block is a nonspecific sign, but is usually the result of chronic organic heart disease. In occasional cases, however, it may be temporary as the result of some toxic effect on the heart or may be produced by coronary thrombosis, or, in rare cases, it may be functional. Although permanent bundle-branch block may be rarely produced by some static focal lesion in a heart otherwise undamaged, in most cases it is an indication of widespread and progressive cardiac damage, and hence its discovery is a relatively serious prognostic sign. However, if the patient survives a year after the discovery of this electrocardiographic abnormality, his prognosis would seem to be considerably improved, since the block is then much more likely to be due to a focal lesion.

Records which show a very minor degree of prolongation of the QRS interval (0.11–0.12 second), especially when associated with high voltage and if unaccompanied by other electrocardiographic abnormalities, may prove very confusing and difficult of interpretation, under such conditions one should avoid a dogmatic interpretation, but should consider the record only in the light of the clinical findings.

One type of bundle-branch block which deserves special mention, because it has only recently been described and because it carries with it a favorable prognosis, is bundle-branch block associated with a short PR interval (0.10 to 0.12 second), occurring in patients with otherwise normal hearts who may be subject to attacks of paroxysmal tachycardia or fibrillation.⁷ Interestingly enough, these individuals usually show normal QRS complexes during the periods of tachycardia, and normal complexes can frequently be induced at other times by the administration of large doses of adrenalin or atropin. The electrocardiograms of this type are usually distinguished by a slurring of the upstroke of R₁, a finding rarely if ever

present in organic bundle-branch block where the delay is in the down stroke. The probable cause of this functional condition is an accessory pathway of conducting tissue between auricles and ventricles (bundle of Kent) which conveys the impulse with great rapidity to a point below the auriculoventricular node. The following case history is cited as an example of this condition and also as an illustration of the harm that a wrong electrocardiographic interpretation can do.

The patient, a 23-year-old student, had had an "attack" a year previously in another city, which consisted of faintness, palpitation and tachycardia, some dyspnea and mild precordial oppression. It had come on while he was playing ball and had lasted about 3 hours. By the time he was seen by his physician, the acute phase of the attack had passed off but his heart was still rapid and irregular. His past history and family background were negative as to any pertinent facts. His physician called a consultant, who saw him at a time when his heart was once more slow and regular. Two electrocardiograms were taken at intervals of a few days, and, apparently largely or entirely on the basis of the electrocardiographic interpretation, a diagnosis of acute myocardial infarction was made. Bed-rest was carried out for several weeks and the patient was then gradually allowed to resume full activity. When I saw him a year later he was feeling quite well, except for the natural anxiety occasioned by the serious prognosis he had been given. At this time a further history of transient attacks of rapid palpitation on two or three occasions, occurring during the course of physical activity, was elicited. Physical examination and x-ray measurements of the heart were completely normal. An electrocardiogram showed left bundle-branch block with slurring of the upstroke of the R wave and a PR interval of 0.11 second. Comparison of the two previous records with this tracing showed them to be essentially the same, since they differed from each other only in minor details of the QRS and T waves. An attempt to change the form of the ventricular complexes by the administration of atropin was unsuccessful, but following the intravenous injection of a very small amount of adrenalin perfectly normal QRS complexes were produced for a few minutes.

It seems quite certain that this young man had the type of bundle-branch block described above, and that the attack which he had suffered a year previously was a paroxysm of auricular tachycardia or fibrillation. The unfavorable prognosis he received was quite unjustified. Much harm could have been averted had the original electrocardiogram been correctly interpreted and the clinical symptoms properly evaluated.

Shift of the Electrical Axis

Frequently but by no means invariably, enlargement of the left ventricle is accompanied by left axis deviation, while right-sided enlargement results in right-axis deviation.

The same findings, however, that occur with cardiac enlargement may, to a certain extent at least,

take place when the position of the heart within the chest is shifted by extracardiac conditions such as high diaphragm, fluid or air in the pleural cavity, or collapse or fibrosis of the lung. With a marked degree of left ventricular enlargement it is not uncommon to find the ST interval slightly depressed in Lead 1 and raised in Lead 3, with an inverted T_1 and an upright T_3 . This pattern is not found when the heart is simply displaced upward and outward by a high diaphragm. Under these circumstances the ST intervals are isoelectric, and the T waves upright, although T_2 may be inverted on occasion.

Myocardial Damage or Disease

Resulting from toxic damage or infection These changes, which are often associated with disturbances of auriculoventricular or intraventricular conduction and with shifts in the electrical axis, are frequently nonspecific so far as the electrocardiographic pattern is concerned. They are manifest by flattening or inversion of the T waves, deviation of the ST interval above or below the isoelectric base line, prolongation of the QT interval and diminution of the voltage of the QRS complexes. These abnormalities may be present singly or in a variety of combinations. Digitalis, for example, typically produces a characteristic spoon shaped inversion of the T waves, whereas quinidine tends to lengthen the QT interval. The QT interval may also be prolonged as the result of toxic states such as uremia and other types of acidosis, in beriberi heart disease, as well as in hypertensive or arteriosclerotic heart disease. Depression of the ST interval with flattening or inversion of the T waves in one or more leads is also seen in beriberi heart disease,⁸ as well as in some cases of severe anemia,⁹ and according to Scherf,¹⁰ the same pattern is commonly found in electrocardiograms of women at the menopause. Severe myxedema typically produces a low voltage in all complexes, and low voltage is also found in myocardial disease of various types. Minor degrees of it may occur in apparently normal people, as has been mentioned above, so that not much reliance should be placed on this sign alone if present only to a slight degree and unaccompanied by other abnormalities.

Resulting from coronary disease and myocardial ischemia The greatest clinical value of the electrocardiogram undoubtedly lies in the information it provides that enables us to diagnose acute myocardial infarction usually associated with coronary thrombosis. The electrocardiographic pattern is often characteristic, and frequently the diagnosis

can be made with certainty from a single record. Yet even here a word of caution is in order against interpreting the electrocardiogram without considering the clinical picture. Even the characteristic pattern of myocardial infarction may be confused with that produced on occasion by pulmonary embolism or by acute pericarditis. Not infrequently atypical changes occur, or the record may be taken either before marked changes have had time to be produced or after they have progressed to the stage when they are no longer specific for an acute lesion. Under these conditions serial electrocardiograms may furnish the information which a single tracing fails to reveal.

In general, the majority of electrocardiographic records taken on patients with a large acute myocardial infarction fall into either the Q_1T_1 or Q_1T_2 type, signifying a so-called anterior or "posterior" infarction.¹¹ These patterns have been well described in the literature as well as in the recent editions of textbooks on electrocardiography, and will not be given here.

Recently the electrocardiographic changes which are found in so-called "lateral infarction" have been described.¹² These consist of depression of the ST segments in Leads 1 and 2 as well as in the precordial lead, especially when the last is placed over the apex. These patients frequently have auricular fibrillation and hence are likely to have received digitalis, which may produce electrocardiographic changes very similar to those resulting from lateral infarction. Moreover, the changes in this type of infarction may disappear rapidly and completely.

As mentioned above, atypical electrocardiographic abnormalities occur which conform to none of the above mentioned patterns. In some cases they have characteristics of a combination of anterior or posterior lesions, while in others they are quite nonspecific and only the changes taking place in serial records, combined with the clinical findings or the autopsy correlation demonstrate that they are in reality due to an infarction. It is not surprising that atypical patterns are sometimes found because not only is the muscular structure of the heart complex, but extraordinary changes in the coronary circulation may take place, with a very varied clinical picture.

It is hazardous to make a prognosis from the electrocardiographic evidence in cases with myocardial infarction. Sometimes one can find evidence that progression of the thrombosis or a new infarction has taken place by the recurrence of acute changes, and, in general, patients whose records show a marked improvement and a return

toward normal within a short period of time have a less severe focal lesion than those whose records do not. But even here prognosis has to be guarded, because one never knows how much disease there may be elsewhere in the heart and the coronary arteries or when another thrombosis will take place.

Electrocardiographic abnormalities which occur as the result of chronic myocardial ischemia secondary to coronary disease may have resulted from an acute cardiac infarction in the past or from slowly developing coronary insufficiency. It is sometimes possible that an acute incident did occur at some time in the past, but on the whole the findings are nonspecific and similar to those resulting from myocardial damage of toxic or infectious origin.

Characteristic traces of cardiac infarction may persist in the electrocardiographic record for the rest of the patient's life. On the other hand, an infarction, and particularly repeated infarctions, may result in a nonspecific abnormality of the electrocardiogram which is indistinguishable from that produced by diffuse myocardial fibrosis secondary to coronary disease without gross infarction—or, indeed, from toxic or infectious myocardial damage.

Resulting from acute pericarditis In recent years a number of articles have been written describing the electrocardiographic changes which may occur in the course of acute pericarditis.^{13, 14} The most striking change that may take place is an elevation of the ST interval in some of or most characteristically in all the three standard leads, and often in the precordial lead as well, especially if it is taken from the right arm to the apex. These electrocardiographic changes are especially apt to be present in purulent pericarditis or hemopericardium, but they may occur in any type of acute pericarditis. They are often present only during the first few days of the pericarditis, and may then disappear in spite of the continuance or progression of the pericardial disease. Changes in the T waves may also occur, these may follow the alterations in the ST segment or may be seen as the initial manifestation. They consist of inversions which occasionally occur in all three standard leads as well as the chest lead, a finding rarely seen in any other condition.

The electrocardiographic abnormalities which are found in acute pericarditis were originally thought to be due to the pressure of the accumulating pericardial fluid exerting a tamponade effect on the heart. Though this may possibly be true in a few cases which show very rapid and marked accumulations of fluid, the more probable explanation in most cases is that they are due to a super-

ficial subepicardial myocarditis, which occurs as the result of the penetration of the pericardial inflammatory process into the superficial layers of the heart.

Since pericarditis is often missed clinically, and since it is so important that purulent pericarditis be diagnosed early and correctly, the electrocardiogram offers a means by which this diagnosis can be made in a considerable percentage of cases.

The condition with which the electrocardiographic changes of acute pericarditis are most often confused is acute myocardial infarction. Although the patterns in the two conditions are in many ways similar, if it is borne in mind that characteristically the ST interval alterations and sometimes the T-wave changes of pericarditis involve all three standard leads, and that changes in Q waves are absent, mistakes in diagnosis are not likely to occur often. It should be remembered that pericarditis may occur in the course of myocardial infarction, and that hence the electrocardiogram may reflect both conditions.

Resulting from pulmonary embolism In 1935 McGinn and White¹⁵ described a characteristic electrocardiographic pattern occurring in certain cases of pulmonary embolism. This consists of the appearance of a prominent S₁ and Q₃, a depression of ST₁ and ST₂ with staircase ascent, and an inversion of T₃ with upward convexity of ST₃. Since the publication of their article a number of reports on this subject have appeared, the latest of which, by Sokolow, Katz and Muscovitz,¹⁶ not only comprises a relatively large series, but also well summarizes the present status of this rather controversial subject. In brief, out of 50 cases they found 5 which fulfilled McGinn and White's criteria. In 9 there were no significant electrocardiographic changes. Twenty-seven showed nonspecific changes, which for the most part consisted of one or more of the abnormalities described by McGinn and White, and in 9 there were present some of the characteristics of recent myocardial infarction, usually of the posterior type. The absence of the full blown picture of myocardial infarction, the failure of the T-wave changes to evolve through a characteristic sequence of changes and the tendency for the abnormalities to disappear made the differentiation from cardiac infarction possible in the majority of cases. There was no correlation between the type of electrocardiographic changes encountered and the nature or extent of the pulmonary infarction.

LIMITATIONS OF THE ELECTROCARDIOGRAM

There are certain questions which the electrocardiogram will not answer. The two most im-

portant are the presence or absence of valvular disease, and the degree of impairment of the cardiac reserve. Since the valves neither convey neurogenic impulses nor have muscle, there is no direct registration of their action on the electrocardiogram. The only evidence that the electrocardiogram ever gives of valvular disease is the indirect evidence suggesting relative enlargement of certain chambers of the heart, which may occur characteristically in various types of valvular disease. The question that is so frequently asked, for example, "This patient has a systolic murmur—does he have mitral disease?" cannot be answered.

The electrocardiogram tells us nothing about the functional capacity of the heart. We cannot judge from it whether a patient is suffering from congestive heart failure or from angina pectoris. A man may be dying from heart failure and still have a normal electrocardiogram and contrariwise he may show a most abnormal record and still be capable of normal activity. It cannot be emphasized too strongly that an electrocardiogram should not be isolated and considered out of relation with the patient himself. As with all information gained in the laboratory, an electrocardiographic interpretation should always be as assessed in the light of the clinical findings.

There are three general types of error which frequently occur when such a clinical correlation is not properly made. First, a normal electrocardiogram may be found in a person who has organic heart disease, and because undue weight is laid on it the correct diagnosis is missed and the patient is improperly treated. Second, an incorrect diagnosis of serious heart disease may be made on the basis of the electrocardiogram alone which has been wrongly interpreted as being pathologic when actually all that was present was artefact, or minor physiologic variation, or change which might be either functional or organic in nature. Third, nonspecific electrocardiographic abnormalities may be wrongly interpreted.

Many of the abnormalities which the electrocardiograph records are nonspecific—that is, they may be produced by any of several disease processes or toxic effects acting on the heart. Moreover certain deviations from the normal which the electrocardiogram may show may be merely extremes of physiologic variations. With the exception of

a very few pathognomonic electrocardiographic findings, mainly concerned with arrhythmias, and to some extent with acute myocardial infarction, an electrocardiogram can be intelligently interpreted and its significance properly evaluated only by considering it in relation to the whole clinical picture and other laboratory findings. Considered in this way the electrocardiogram offers much that is of value. When it is taken out of its context and too much stress is laid on it the dangers resultant from an unwise interpretation are as great as is the helpful information it provides.

Erratum. In the "Report on Medical Progress Pathology," by Dr. Tracy B. Mallory, in the May 30 issue of the *Journal* the sentence starting on line 17 of column 2 on page 924 should read as follows:

The rate of healing was found to be inversely proportional to the size of the infarct and directly proportional to the adequacy of the remaining coronary circulation.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

CASE 26261

PRESENTATION OF CASE

A fifty-six-year-old Danish housewife was admitted to the hospital for study

The patient had enjoyed good health until two years before admission when several of the following symptoms appeared almost simultaneously. Possibly the first symptom in its order of appearance was that of pain in the lower thoracic region of the spine, which radiated forward toward the midline beneath the breast on the left side. She complained of "sticky" pains over the left chest anteriorly, occasionally precordial, lasting sometimes five minutes and accompanied by palpitation and shortness of breath. Dyspnea with exertion was noted from such bland acts as walking slowly out of doors or bending over while at work in her home. Hair appeared on the upper lip and became quite noticeable, as did that on the side of her face, at the same time the hair on her head came out in "bunches." Approximately one and a half years before admission she began to notice flushing of the face and neck and the skin showed eruptions which appeared to have been acneform. All these symptoms persisted and increased in severity. It then became difficult for her to talk. She became worried about her symptoms and a physician was called.

Roentgenograms of the chest showed cardiac enlargement. The physician then prescribed "green pills," which she continued taking until one week before admission. She was sent to an outside hospital four months before admission, where she stayed for more than two months and was then referred to a sanatorium. During this time edema of the ankles appeared and her eyes began to "water." She was referred from the sanatorium to this hospital for further study.

The patient came to the United States at the age of eighteen. She had had the usual childhood diseases, but no scarlet fever or diphtheria. At the age of twenty-two she had had typhoid fever, with an uneventful recovery. There had been no other illnesses of any significance. The patient

weighed about 144 pounds, and there had been no recent change. Catamenia began at the age of sixteen, occurred once every twenty-eight days, lasted one week and tended to be profuse. She had had the menopause at the age of forty-five. There had been no discharge or bleeding since that time. She had been married at the age of twenty-seven and had had six children, one of whom died at an early age of heart disease. The remaining children and husband were living and well. The family history was negative.

Physical examination revealed a short, stocky woman whose face, neck and upper thoracic regions were flushed. The hair was soft, fine, sparse and greasy. There was a rough, stubby growth of hair over the face, upper lip and chin, where the patient had recently shaved. No abdominal striae were noted. The skin showed multiple acneform lesions over the upper chest anteriorly. The heart was somewhat enlarged to the left. The signs were muffled, and no definite murmurs were audible. The blood pressure was 170 systolic, 100 diastolic. There were rales at both lung bases. The spleen was just palpable with the patient on the left side. There was a right dorsal, left lumbar scoliosis. Examination of the genitalia revealed that the mucous membranes were "highly colored." There were many redundant vaginal folds, and because of this the cervix was not visualized. The clitoris was slightly larger than normal. The visual fields were normal. The fundi were not well observed. The neurological examination was negative.

The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 5,500,000 with 78 per cent hemoglobin (Sahli), and a white-cell count of 11,400 with 65 per cent polymorphonuclears, the smear was normal. Examination of the urine was essentially negative. The plasma volume was 2554 cc, or within normal limits, and the extracellular fluid volume was 12,370 cc, a low normal. The weight was 139 pounds. A blood Hinton test was negative. The blood sugar was 110 mg per 100 cc, the plasma nonprotein nitrogen 26 mg, the serum calcium 9.7 mg, the serum phosphorus 3.2 to 4.0 mg, and the serum phosphatase 5.24 units. A glucose tolerance test by the venous capillary method, using the macro and micro techniques, showed an elevated flat curve during the four hour interval of the test. The urinary samples taken during the last two, three and four hours

showed yellow-brown and green tests with Benedict's solution. The second, third and fourth blood macro tests on the blood gave readings of 412, 304 and 250 mg per 100 cc. respectively. The micro tests were similarly elevated. The phenolsulfone phthalein test showed 40 per cent excretion in thirty minutes and 65 per cent in one hour. The plasma chlorides were equivalent to 102 cc. of N/10 sodium chloride per liter, the carbon dioxide combining power was 74.0 vol per cent, the total cholesterol 144 mg per 100 cc., and the serum sodium 147.9 milliequiv per liter. A urinary female sex hormone test was slightly positive. An electrocardiogram showed a ventricular rate of 85 with frequent auricular premature beats, a PR interval of 0.14 second, a QRS duration of 0.12 second, left axis deviation and left bundle-branch block.

Roentgenograms of the spine showed marked scoliosis of the upper dorsal spine to the left and of the lower dorsal spine to the right, with corresponding deformity of the rib cage. Chest plates showed the diaphragms high in position, particularly on the left, with the heart in the transverse position. The heart was enlarged in the region of the left ventricle. There was a markedly tortuous, elongated aorta without gross dilatation. The lung fields were clear. The visible bones appeared decalcified. There was marked development of the subcutaneous fat. A flat film of the abdomen showed the left kidney displaced markedly downward and located so that it was seen end on. The displacement was produced by a round 15-cm soft-tissue mass which occupied the place between the displaced kidney and the diaphragm. The spleen was displaced laterally. In the lateral view about three fourths of this tumor lay in the front of the spine and one fourth lateral or posterior to the lumbar vertebral bodies, the posterior aspect of the tumor lying against the descending posterior part of the diaphragm. After intravenous injection of dye there was prompt excretion on both sides. The kidney pelvis appeared to be normal. A film of the skull showed no gross evidence of disease. In roentgenograms following air injection the right perirenal tissues and adrenal gland were fairly well visualized. The adrenal gland appeared slightly larger than normal, and its density was approximately that of the kidney. On the left there were comparatively small amounts of air visible surrounding the kidney, as well as a tumor mass in the region of the

adrenal gland. The mass was separated from the diaphragm by air with the exception of a small space in the center of the diaphragm. The mass appeared lateral and anterior to and well separated from the spleen. By a gastrointestinal series, the mass displaced the stomach forward and slightly toward the right. Occasionally the stomach was displaced even more laterally, thus showing that it was not adherent to the mass though it must have been in close contact.

Further data obtained while in the hospital revealed that the patient had suffered with paroxysmal nocturnal dyspnea, ankle edema and precordial pain that was brought on by effort, especially after meals, and was relieved by rest. These symptoms were associated with dyspnea and were minimal after the three months period of hospitalization before admission. The patient was placed on $1\frac{1}{2}$ gr of digitalis daily, was given intravenous Salyrgan twice each week and treated with bed rest. She continued to show rales at both lung bases, but there was no evidence of peripheral edema. The blood pressure remained around 170 systolic, 90 diastolic. A tourniquet test performed with the blood pressure at this level showed no petechiae on immediate release of the tourniquet.

Approximately one month after admission a right adrenal exploration was performed. A very small normal adrenal was found and biopsied. The postoperative course was uneventful. Some two weeks later left adrenal exploration was performed.

DIFFERENTIAL DIAGNOSIS

DR. AUBREY O. HAMPTON: You can see this large mass in the lateral view displacing the stomach forward and medially. The intravenous pyelogram shows the upper pole of the kidney at the third lumbar vertebra. The mass is smooth and rather oval, and the shadows of the spleen and of the upper pole of the kidney can be definitely separated from it. There is probably one correction that should be made in the statement about the air injection, that is, the right adrenal is not distinctly seen. There is a round shadow in the region but it does not look like that of the adrenal gland. It does not fit the top of the kidney.

DR. ALFRED O. LUDWIG: How about the degree of decalcification?

DR. HAMPTON: For a woman of that age, I should not get too excited about it. There is a fair amount but nothing unusual.

DR. LUDWIG: The x-ray findings localize the dis-

turbance in the region of the adrenal gland. This patient presented a picture which may have been caused by a number of different conditions. In the first place we have symptoms that appear to have been secondary to the hypertension, with some myocardial involvement and very mild cardiac failure. The electrocardiogram showed evidence of myocardial damage insofar as she had left bundle-branch block.

The most striking symptoms are those referable to the endocrine system. She noticed the appearance of hirsutism, and some difficulty in speech, which is not specified. What was the change in speech?

DR OLIVER COPE: Not much more than language difficulty.

DR LUDWIG: I should have liked to have had you say her speech was hoarse and deep, but that apparently was not the case. This all appeared about eleven years after the menopause in a woman who had had a perfectly normal menstrual history and had borne six children. Physical examination showed a little obesity and general hirsutism, with soft fine hair and marked increase in facial hair, so that she had to shave. There were also acneform lesions of the skin. All these symptoms and signs could occur with an adrenocortical tumor, and it seems to have been localized by x-ray studies, particularly following air injection.

In regard to the laboratory work there was an increase in the red-cell count to 5,500,000, these cases of adrenocortical tumors may show considerable polycythemia. The blood volume was apparently normal, but there have been cases reported in which it was decreased. The sugar tolerance was decreased—a common finding in this type of tumor. The serum calcium and phosphatase were normal, one phosphorus value was on the low side, but she did have values as high as 4 mg per 100 cc, which is normal. The chlorides were normal. There was good renal function as shown by the phenolsulfonephthalein test. The serum sodium was slightly elevated, the cholesterol within normal limits, and the carbon dioxide combining power high.

The main problem in seeing this patient for the first time would be to establish a diagnosis, and the differential diagnosis that I should consider lies between Cushing's syndrome, or pituitary basophilism, and adrenocortical tumor.

Should any other disturbances be considered? One that occurs to me is arrhenoblastoma, an ovarian tumor that is also associated with hirsutism, but with an otherwise different picture, the arrhenoblastoma being a masculinizing tumor.

Hirsutism occurs to be sure, but there may also be loss of hair with baldness, and atrophy of the breasts and genitalia, except for the clitoris and labia majora, which increase in size. Polycythemia is usually present. Acne of the skin is not found, nor are there marked changes in the bones. Usually there is a weight loss rather than obesity, although at times fat deposits may occur. With this type of tumor the diagnosis is usually made by palpation of a pelvic tumor in the region of one ovary, the uninvolved ovary being impalpable. The sugar tolerance may vary, but it is usually not decreased. The blood pressure and basal metabolic rate may also vary, and give no direct clues. The Aschheim-Zondek test is usually negative.

So far as Cushing's syndrome is concerned, I can suggest no method other than perirenal air injection to differentiate clinically between Cushing's syndrome, or basophilic tumor of the pituitary, and adrenocortical tumor. Obesity, hirsutism, decalcification and genital changes with enlargement of the clitoris occur in both. In one case that I looked up, Dr. Cushing stated that increase in the size of the clitoris was not so common in the pituitary as in the adrenal cases, but that does not seem to be generally true as some of the former have been reported with enlargement of the clitoris. In adrenocortical tumors the symptoms that appear depend on the time of life in which the tumor occurs. These are usually tumors of the adrenal cortex, either adenomas or occasionally carcinomas. They may occur in males before puberty, producing the so-called infantile Hercules type with premature growth of hair and enlargement of the genitalia. Male hormones appear in the urine, except in boys under the age of ten, there is rapid growth but later a cartilage loss so that these individuals may be shorter than normal. They tend to be obese. The same syndrome also may occur in young individuals with pineal tumors. In males after the age of puberty adrenal tumors may occur without any symptoms, but endocrine disturbances may begin with polydipsia, hypertrophy of the genitalia or changes in metabolism, usually with increase in secondary sex characteristics tending toward feminism. In females before puberty the cases reported have tended toward pseudohermaphroditism and toward adult masculinity with increased hair growth, increase in the size of the clitoris and labia majora, absence of menstrual periods and change in voice toward the masculine side. Adrenal tumors in females may occur without any endocrine symptoms, and when they do exist they again tend

toward masculinization, with amenorrhea. There may be baldness. The excess hair tends to fall out after the tumor is removed. The genital changes are marked in young patients: the ovaries are small, the clitoris and the labia majora large, the breasts atrophied. Sterility is present, but there are cases in which pregnancy has occurred after the removal of the tumor.

The diagnosis of adrenocortical tumor depends on this technic of air injection which Dr Cope can tell you more about than I. Before that was done the only way to prove the presence or absence of these tumors was by exploration of the adrenal glands. There are a few other points which I cannot discuss adequately, such as the assay of androgenic substances in the urine, which in the presence of some of these tumors increase markedly, although I understand there are some cases in which the androgens are normal. These syndromes may also occur from hyperplasia of the adrenal cortex without the presence of tumor. There are a few other clinical points of differentiation which have been suggested. I do not know how valid they are, but it is said that the pituitary type of hirsutism is lanuginous as contrasted with the ovarian type which is universal and masculine in distribution and the adrenal type which is said to be a growth of coarse dark hair with wide distribution. Pituitary obesity is said to be of the girdle type, ovarian obesity is more general and adrenal obesity tends to involve the face, neck, and body and to be less marked in the extremities. I should like to hear from someone better versed in endocrinology as to the possible significance of hormone tests in the differential diagnosis of these various conditions. I shall make a diagnosis of adrenocortical tumor.

Dr. COPE: It is a difficult case to discuss since the diagnosis is so obvious, but it was not quite so obvious as the record implies. Before the patient came to us she passed through many hands at first she was classed as a cardiac patient and then as someone suffering from general malignancy. One of our former surgical houseofficers first suspected the diagnosis. She shows a combination of the virilism syndrome, if I may call it such, and basophilism. Complete hormonal studies were not done because 17 ketosteroid assays were not available when she was here two years ago. Have not assays been subsequently done on the urine which had been kept?

Dr. ANN T. FORBES: Yes, she had a high titer, 70 mg

Dr. COPE: A titer of 70 mg in twenty-four hours is nearly tenfold more than the average normal woman would show at this age, the upper limit being around 12 to 13 mg.

The surgeon was presented with a problem, and I should like to point out the usefulness of the air injection technic. We did not inject air merely to demonstrate a tumor that was obvious in the plain film. In a person of this age the tumor might well be malignant, and we were therefore interested to know whether the tumor was adherent—the more adherent the less likely we could excise it in toto. After injection you can see the air surrounding the tumor in various views, both on the lateral and anterior plates. The air surrounded the tumor except for one area. We could, therefore, conclude that the tumor was resectable. That is one definite use for air injection.

Dr. Hampton brought out a second point, which is not in the original record. When we did the injection we considered this shadow on the right might be the adrenal gland. None of us would make such a statement now because of the absence of characteristic form—it is fat rather than the adrenal gland. The record from which this abstract was prepared states that there was probably a normal adrenal gland on the right, just below the liver. We were not sure, however, and the right side was explored first, the reason being that excision of an adrenocortical tumor in toto is followed by a very high mortality which in the literature is between 30 and 40 per cent. It is my belief that this mortality is due directly to acute adrenocortical insufficiency. With the excessive secretion from the tumor on one side, the normal adrenal gland on the other side atrophies from disuse, and at the time of operative removal of the tumor, there is insufficient normal adrenal tissue left to continue normal function. So the first thing in this patient was to explore the right adrenal gland.

As the record states, a very small right adrenal gland was found. Three weeks later the large adrenocortical tumor on the left was exposed, and a subtotal excision performed. I did not believe there was enough adrenal cortex on the right side to carry on the normal requirements for cortical hormone, so I left a portion of the tumor behind. Today we should give desoxycorticosterone acetate preoperatively, but this synthetic substance was not available at that time.

Dr. LUDWIG: I should like to ask Dr. Cope to state the difference between pituitary basophilism

and adrenal tumor from the hormonal point of view

DR COPE So far as I know one cannot We have had one patient with an ovarian arrhenoblastoma, for example, who had a normal 17-ketosteroid excretion

DR LUDWIG Most cases of pituitary basophilism have either hyperplasia or adenoma of the adrenal cortex as well

DR COPE At the Peter Bent Brigham Hospital Dr Joseph C Aub has studied a girl who has been completely rid of basophilism following x-ray treatment of the pituitary gland, and I believe there is a primary disease arising in the pituitary gland as well as in the adrenal cortex By the tests that have so far been devised, no method has been found to differentiate physiologically these true cases of pituitary basophilism and those of adrenocortical basophilism The virilism syndrome is also unsettled One of our patients with an arrhenoblastoma showed a normal urinary excretion of 17-ketosteroid for a woman of her age This is an extraordinary observation because she was a masculine type of woman with amenorrhea, after the removal of the tumor the menses returned promptly and she became pregnant Such a woman must obviously have a masculinizing hormone that we do not pick up by the present methods It may not appear in the urine as an ordinary androgenic steroid In the same way we cannot differentiate various types of adrenocortical tumors presenting different clinical pictures—all the way from masculinization to basophilism In other words, although the laboratory has made tremendous advances it is by no means able to tell us in a given patient which gland is diseased

CLINICAL DIAGNOSIS

Adrenal tumor, left (2 type)

DR LUDWIG'S DIAGNOSIS

Tumor of the left adrenal cortex

ANATOMICAL DIAGNOSES

Carcinoma of adrenal cortex, left, with metastases to periaortic nodes

Pulmonary embolism, right

Bronchopneumonia

Cardiac hypertrophy, hypertensive type

Arteriosclerosis, moderate, aortic and coronary

Hirsutism

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN This tumor weighed about 1000 gm and showed histologically a characteristic adrenal-cell carcinoma Much of the

tumor was necrotic Unfortunately the patient died a few days later from massive pulmonary embolism and bronchopneumonia At autopsy we found in the region of the left adrenal gland a necrotic mass of tissue about 7 by 3 by 2 cm, which microscopically showed necrotic carcinoma The other adrenal gland, although small, appeared normal The regional periaortic lymph nodes were replaced by tumor This is the fourth case of adrenal-cell carcinoma that we have seen here during the past five years One patient had all the symptoms of Cushing's disease, and the negative response to irradiation of the pituitary gland was the only clue to the correct diagnosis¹ The other two cases presented no endocrine changes One was that of a young woman of thirty, who entered because of a mass in the left upper quadrant which was clinically diagnosed as splenomegaly The tumor was removed, and one year later a recurrence in the region of the transverse mesocolon was also removed She gave birth to a baby during the next year, but when last seen, about a year and a half ago, an exploratory laparotomy revealed a huge inoperable recurrence in the left upper quadrant, with metastases to the periaortic lymph nodes The other non-functioning tumor was removed from a forty-three-year-old man who entered the hospital with signs and symptoms of a Brodie's abscess of the tibia, which operation revealed to be a metastatic tumor consistent with one of adrenal origin² The primary adrenal tumor was removed, and a Gritti-Stokes amputation of the leg performed The patient was followed in the Out Patient Department and was doing well until two and a half years after operation, when a large, apparently recurrent, mass was discovered in the left upper quadrant A course of x-ray treatment, totaling 2100 r, was given without any apparent change in the size of the mass When last seen, two months ago, more than three years after operation, the mass was still present, but a chest plate was negative and the patient was feeling quite well

CASE 26262

PRESENTATION OF CASE

A thirty-two-year-old white, African born, WPA worker was admitted to the hospital because he had been "seeing things" for three weeks

The patient was brought to the hospital by his brother and a friend. The history obtained from them was vague and incomplete. It was stated that the patient had been a heavy drinker of alcoholic beverages for many years and had been treated for delirium tremens on two occasions. Three weeks before admission the patient had experienced what appeared to be visual hallucinations, as he saw "cats, dogs, people's faces and so forth. He had been "irrational and out of his head. On occasions he talked normally while immediately thereafter he changed to an entirely unrelatable subject. His irrationality and confusion as well as hallucinations increased for a few days before admission. He was apparently found by the police of an outside community and was taken to the office of a physician, who made a diagnosis of acute alcoholism and stated that the patient had suffered from exposure. He was then referred to this hospital for additional treatment. No further history was obtainable.

On admission the patient was irrational. He was restless, picked at the bed clothes, seemed tense and apprehensive and "jumped at a touch. There was no speech defect, he had visual hallucinations of "cigarettes and "pieces of wood" in his hands, but denied others. He believed that he was in a club and that the date was 1930. He could not give his name, but gave his age and address correctly. He was able to perform simple calculations. His attention was held with difficulty, and recent memory was impaired. The speech was usually irrelevant and partly incoherent. He stated that he fell on the day before admission and struck his head, but gave no other history of trauma. He denied ever having taken drugs.

Physical examination revealed a restless, overactive, jumpy and delirious man. There were fine tremors of both hands, and he continually grasped at imaginary objects. The general examination showed no apparent head or body injuries. The tongue was dry and coated, the throat was red but there were no localized areas of exudation. A postnasal drip was evident over an extremely dry, beefy red pharynx. The upper teeth had been removed, the lower teeth were carious. There was a moderately loud systolic murmur over the apex of the heart. The blood pressure was normal. A few dry crackling rales were heard on deep inspiration at the bases. Examination of the abdomen was negative. The liver was palpable 2.5 cm. below the costal margin in the right midclavicular line, its edge was not tender. A rectal examination was

negative. The genitalia were negative except for the presence of genital warts on the shaft of the penis. There were abrasions over the elbows and scars over the lower legs, but otherwise the extremities were normal. Both pupils were dilated and fixed to light, the left was slightly larger than the right (the patient had received "drops" from a physician the day before, for examination of the evertgrounds). The remainder of the cranial nerves were normal. Both calf muscles were tender bilaterally. Sensation was normal. The abdominal, Hoffmann and cremasteric reflexes were absent. The knee jerk on the right was slightly more acute than that on the left. The plantar reflexes were down. The Gordon and Oppenheim tests were negative. Cerebellar functions could not be tested. The neck was stiff, and there were bilateral Kernig signs.

The temperature was 100.2°F., the pulse 120 and the respirations 26.

Examination of the blood showed a red-cell count of 4,500,000 with 80 per cent hemoglobin (Tallqvist), and a white-cell count of 12,500 with 94 per cent polymorphonuclears; the smear was normal. The urine examination was negative save for the presence of a ++ albumin test. The blood Hinton test was positive, the blood Wassermann test weakly positive. The serum protein was 5.3 gm. per 100 cc., the serum nonprotein nitrogen 11 mg. The blood serum bromide examination was negative. A lumbar puncture showed an initial pressure equivalent to 200 mm. of water, with moderate cardiac and respiratory excursions. About 5 cc. of xanthochromic fluid was removed, with a final pressure of 105 mm. A cell count showed 300 lymphocytes, 100 red blood cells (crenated) and 15 polymorphonuclear cells per cubic millimeter. The Pandy test was ++, the total protein was 618 mg. per 100 cc., the gold sol test was 0001223321, the spinal-fluid Wassermann test was negative. The spinal-fluid sugar after another lumbar puncture was 36 mg. per 100 cc.

Röntgenograms of the chest showed no definite evidence of disease, although the skull showed a very questionable fracture line in the posterior parietal region. The findings, however, were said to have been not sufficient for diagnosis.

The patient remained in the hospital some fifty odd hours, during which time he ran a continuous temperature above 102°F. He remained partly disoriented and required active sedation and restraint. He was given large doses of nicotine acid and thiamin chloride, and fluids were

forced In spite of all efforts of therapy, however, the patient expired early on the morning of the third hospital day It was stated that his respirations suddenly became "rapid," and by the time a physician had arrived he was dead

DIFFERENTIAL DIAGNOSIS

DR MERRILL MOORE* I do not need to tell you that this is a difficult case We might attempt in a logical way to rule out some of the more obvious possibilities We know that this man was alcoholic That is definitely stated by the informant and is probably the most obvious fact with which we have to deal, and it would be convenient if we could relate his final illness to his alcoholism When we consider the causes of death in chronic alcoholism we recall that patients do die with no more specific diagnosis than delirium tremens, although there we are not very sure of the exact way in which death occurs—possibly with a general disturbance of body metabolism and disturbances in the cerebral circulation We also find such patients dying of what is now beginning to be diagnosed clinically as Wernicke's disease, and there too the exact cause of death is not clear, although at autopsy the findings are usually more definite and more demonstrable than they are in delirium tremens And we also know that alcoholism is a "smoke screen," that excessive drinking is often the result of psychological or social disturbances and that excessive drinking can and often does mask organic disorders of a serious nature, for the chronic alcoholic patient is very difficult to examine He is usually unco-operative, he is often beclouded mentally, and unless one is accustomed to examine them, alcoholism can often mask neurological disturbances The examination of the eyes is often difficult, and so are tests for muscle tone We must remember that sometimes there can be absolutely no dependence on the examination, and that it is always possible for the examination to be inadequate Therefore, before assuming that this patient died either of delirium tremens or of Wernicke's disease, we have to consider very carefully the very definite changes in the spinal fluid that are not entirely compatible with either diagnosis, accordingly, I should like to begin an attempt at a differential diagnosis in this case by saying that it does not seem to me that this patient died of delirium tremens or of Wernicke's disease

The second point we must keep in mind in attempting to approach a diagnosis is that this patient does give a history of a fall How reliable it is

we do not know, but it is a part of the history that we cannot ignore, and I think we should not exclude it as a possible factor in his illness We have to consider subdural or possibly intracerebral hemorrhage, and although the x-ray plate alone is not sufficient for diagnosis, it does bring up the question of a linear fracture We know that alcoholic patients are very prone to have subdural hemorrhage, but if we assume that this patient did have one, we have to admit that the spinal-fluid findings in this case are unusual for such a diagnosis, although the pressure is rather high and there is an excess of white blood cells in the spinal fluid In uncomplicated cases of subdural hemorrhage, we do not ordinarily see this except in conjunction with other or concomitant intracerebral hemorrhage due to trauma If we try to tie up the whole history with the patient's alcoholism, we should think of subdural or intracerebral hemorrhage as a result of a fall the patient may have had while intoxicated, and consider that as one possible cause of death But furthermore we have to consider the possibility as to whether this patient's terminal illness bore no relation at all to alcoholism, which is also quite possible If this were so, what could the other disturbance be?

There is much in his illness to suggest that the terminal illness was not related to alcoholism and that he might have died, and probably did die, of some more or less acute febrile illness If we are to admit that possibility, in spite of the weakly positive blood Wassermann test, the positive blood Hinton test and the negative spinal-fluid Wassermann test, we have to consider, first, tuberculous meningitis, since the spinal fluid contained 300 lymphocytes, 15 polymorphonuclear cells, a total protein of 618 mg and a sugar of 36 mg At that point we must remember that it is unfortunate that we do not have more spinal-fluid examinations because they would be extremely helpful in differentiating the various types of meningeal reaction that this patient may have undergone They would be a great deal of help in making an accurate differential diagnosis

Other possibilities could be an intracerebral hemorrhage, not related to trauma, which might have been located near one of the ventricles and which might thereby have caused softening of the ventricular wall and might have given rise to a meningeal cellular reaction in the spinal fluid This could explain the high cell count and the high protein This lesion might have occurred in one of the silent areas, in the frontal area or even in the basal cerebellar region I do not believe that I can make any more definite diagnosis of this

*Associate in psychiatry Harvard Medical School

case without an autopsy. It is possible that one might be made if more careful and repeated clinical examinations had been possible and if more spinal fluid examinations had been made. I can say very definitely that I do not believe that this man died of alcoholism alone and that there was some complicating factor in the nervous system, which might have been a subdural or intracerebral hemorrhage from trauma, an intracerebral hemorrhage without trauma or, more probably, an acute meningeal reaction of the tuberculous type. The negative spinal-fluid Wassermann is strongly indicative that it was not an acute syphilitic meningitis. The only recent case of subdural hemorrhage in an alcoholic patient that we have seen had spinal fluid findings similar to those in this case but also had an intracerebral hemorrhage near a ventricle. We should not close the discussion of this case without mention of the remote possibility of brain abscess or new growth although the history is rather acute in its onset for such a diagnosis and no focal area is suggested by the patient's history or examination.

DR. RICHARD SCHATZKI: There are two lateral portable films of the skull apparently taken a few hours before he succumbed, when he was in a very unco-operative state. There is no reason to suppose they would show anything but the gross pathology. A question might be raised as to whether it is justifiable to subject a patient to examination of the skull when so little is to be expected, the procedure is at times not without danger to the patient.

DR. MOORE: Was another Wassermann test done?

DR. MALLORY: Not on the spinal fluid. The blood Hinton was checked.

DR. JAMES B. AYER: I do not remember this case. I think Dr. Moore is on safe grounds when he says there is something besides alcoholism

As I read the case it seemed to me there must have been hemorrhage, and I should rather like to place it at the base, probably a meningeal hemorrhage at the base. With fractures at the base of the skull we see that fatal type of hemorrhage which may seep into the basal cisternae, may give a high spinal fluid protein and a rhinorrhea and does not show by x-ray except rarely. With the high protein and the increased cells, I also wonder if infection from the nasopharynx has not occurred.

DR. MOORE: You interpret the postnasal drip as the result of a basal fracture?

DR. AYER: It could be.

DR. MOORE: Yes, it could be.

CLINICAL DIAGNOSES

Delirium tremens

Meningitis?

Intracranial hemorrhage?

DR. MOORE'S DIAGNOSIS

Tuberculous meningitis.

ANATOMICAL DIAGNOSIS

Tuberculous meningitis

Miliary tuberculosis

PATHOLOGICAL DISCUSSION

DR. MALLORY: There was no fracture of the skull, and no hemorrhage was found. The meninges at the base were quite cloudy, and there were some suggestive tubercles on gross examination. On microscopic examination there was quite clearly a tuberculous meningitis. Miliary tubercles were found in considerable numbers throughout the viscera, and the meningitis was unquestionably secondary to a generalized miliary tuberculosis.

CONGRATULATIONS

THE *Journal* extends congratulations to Dr. Frank Howard Lahey, of Boston, because of his designation as president-elect of the American Medical Association, and to the House of Delegates because of the wisdom of its choice.

The American Medical Association was organized in 1847, and during the first fifty years, six New England physicians—four from Massachusetts and two from Connecticut—served as presidents. Of the former, the first was John Collins Warren, of Boston, who was elected in 1849. David Humphrey Storer, of Boston, was chosen in 1866, Henry Ingersoll Bowditch, of Boston, in 1877, and Henry Orlando Marcy, of Cambridge, in 1892. To serve during the next forty-five years, only one New England representative was selected,

—Herbert Leslie Burrell, of Boston,—and he held office in 1908, thirty-two years ago.

In view of the prominence of Boston as a medical center, in view of the responsible positions held by its physicians in the various societies devoted to medicine, surgery and the medical specialties and in view of the many excellent physicians scattered throughout New England, it has been difficult to understand why only one physician from this section of the country had been elected to the presidency of the American Medical Association in forty-eight years. Perhaps Yankees, in general, are uncompanionable, and perhaps Bostonians, in particular, are a bit complacent. So far as Dr. Lahey is concerned, his innumerable friends all over the United States refute the former, and the views expressed in his published papers and unpublished speeches negate the latter. This acquaintance and this broadmindedness, together with his well-recognized ability as a surgeon, as an administrator and as a teacher of physicians, make the choice of the House of Delegates a happy one.

PROLONGED RESIDENCIES THEIR EFFECT ON THE PRACTICE OF MEDICINE

THE effect of prolonged residencies on medical education and on hospitals has been considered in the June 13 and June 20 issues of the *Journal*. The third and final problem—that of their effect on the practice of medicine—presents obvious difficulties, such an effect or effects will not be experienced immediately, and it is hazardous in the extreme to attempt to predict them. The effort is not without interest, however, and some of the premises, at any rate, may be agreed on regardless of whether or not the conclusions seem acceptable.

The product of the new system will certainly be a much more highly trained man than the majority of his predecessors. He will have had an intensive clinical experience with hospital medicine but not the slightest experience with practice. Five years of semi-monastic institutional life with consultants, nurses, laboratories, dietitians and social service workers at his beck and call are hardly the best of backgrounds for adaptation to an individ-

ualistic, competitive medical practice. Having passed the age of thirty, he finds himself cast loose into the community without a contact that might reasonably bring a patient to his office. His erst while classmate in college, who sensibly decided to sell bonds, is seriously concerned about the preparatory school to which the son should be sent. It is only reasonable to suppose that any offer of immediate financial security will prove almost irresistible to him, and that the numbers of full-time salaried specialists—and by the newer definitions this will certainly mean surgeons and probably internists—will be increased by his accession. Accustomed for so many years to constant consultative association with other specialists, he will also start with a strong tendency toward group medicine rather than toward individual practice.

In line with this, and as another by-product of the new system, and of the boards of certification, which have done so much to bring it into effect, there will be an increased sharpness in the division between practitioner and specialist. As adequately trained men become more numerous and as the criteria of such training become recognized more generally it will be increasingly difficult for men to shift from the first status to the second. To a large extent this will be a safeguard to the members of the community, who will thus be protected from untrained, self-styled "specialists." There are potential liabilities, however. Even an inadequate surgeon or roentgenologist is far better in an emergency than no surgeon or roentgenologist at all. It is to be hoped that requirements and regulations preceding certification will not be pushed to such an extreme that small communities which cannot support a variety of fully qualified specialists will be deprived of essential services.

Furthermore, it is most important that the specifications of training shall not become too rigid. There is gentle irony in the fact that men who to a large extent were self-taught believe that their successors cannot achieve an education in the same manner. Instruction is a short cut to knowledge properly imparted and assimilated it will greatly accelerate the acquisition of knowledge and will prevent many a needless mistake, but all the in-

struction in the world will never eliminate the need for self-education. It is fair enough to demand proof of qualification, but the gateway must never be closed to the man who chooses the unconventional and original approach. By present standards Harvey Cushing's training in brain surgery was shockingly inadequate!

MEDICAL EPONYM

CHADWICK'S SIGN

James R. Chadwick (1844-1905), of Boston, made no claim to be the discoverer of the diagnostic value of the bluish discoloration of the vaginal mucous membrane which occurs in pregnancy, but in an article appearing in the *Transactions of the American Gynecological Society* (11:399-415 1887), entitled "The Value of the Bluish Coloration of the Vaginal Entrance as a Sign of Pregnancy," after referring to previous observers of the phenomenon, he states:

In scrutinizing the color of this part in a large number of women I early discovered that while in the majority the bluish tinge appeared over the whole vaginal entrance, there was a fair proportion in which the violet tint was confined to the anterior wall of the vagina, just below the urinary meatus, whence it shaded off into the normal pink color laterally. This, when distinctly perceptible I soon found to be, in my practice, an absolutely sure sign of pregnancy. There were, furthermore, a very few in whom the blue tint was universal but more accentuated on the posterior wall of the vaginal entrance, which I found was valueless as a sign of pregnancy unless the color was quite deep. The recognition of this peculiar localization of the blue tint on the anterior wall as a sure sign of pregnancy I feel is the most important new point in this communication.

MASSACHUSETTS MEDICAL SOCIETY

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., Secretary
330 Dartmouth Street
Boston

PYELITIS OF PREGNANCY

Beginning with the May 2, 1940, issue pyelitis of pregnancy has been discussed in the *Journal*. The cases of former years emphasized symptomatic treatment: rest in bed, urinary antiseptics

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

and forced feedings. The prognosis of the immediate attack was always good. The disease might well recur during pregnancy, but the opinion was held that after delivery the kidney infection spontaneously cleared up with no subsequent damage. We know that this is not always the case—that pyelitis of pregnancy is very frequently followed by permanent kidney damage. As cystoscopy and kidney lavage became common practices in urology, their use in diagnosing and treating renal disease during pregnancy naturally followed. Cases have been presented showing distinct improvement following this form of treatment, the acute attacks subsided much more quickly than they did under symptomatic treatment, and subsequent exacerbations were not so common.

The present era of chemotherapy includes the field of kidney infection. Mild cases have responded remarkably well to this type of therapy, and such results may lead the medical profession to disregard the value of intravenous pyelograms, cystoscopy and kidney lavage, occasionally to the detriment of the individual patient. All cases of pyelitis of pregnancy which do not respond to supportive treatment should be seen by competent urologists before chemotherapy is instituted. Sulfanilamide and its allied compounds are not fool-proof drugs, and their administration should never be undertaken by one who is not versed in their use. The patient's health will best be served by an appreciation of this fact by general practitioners and by obstetricians.

In the series presented no cases have been reported in which there was the need for interrupting pregnancy because of pyelitis, however, twenty or twenty-five years ago this was not uncommon. Early diagnosis, early consultation, kidney lavage, if necessary, and chemotherapy should make this procedure entirely unnecessary except in cases already presenting irreparable kidney damage. It is also possible that chemotherapy may reduce very materially the permanent kidney damage that we now know so frequently followed attacks of pyelitis during pregnancy.

The subsequent series of cases will deal with pneumonia as a complication of pregnancy.

DEATHS

HAYES—**WILLIAM F. HAYES, M.D.**, of Beverly, died April 4. He was in his fifty-ninth year.

Dr. Hayes received his degree from Tufts College Medical School in 1909 and was a member of the Massachusetts Medical Society and the American Medical Association.

PEASE—**EDWARD A. PEASE, M.D.**, of Pasadena, California, died June 19. He was in his seventy-sixth year.

Dr. Pease received his degree from Harvard Medical School in 1892 and was a fellow of the Massachusetts Medical Society and the American Medical Association.

RUGGLES—**EDWIN P. RUGGLES, M.D.**, of Dorchester, died June 19. He was in his sixty-eighth year.

Born in Milton, he received his education at Springfield College and the University of Iowa, and obtained his degree from Boston University School of Medicine in 1900. He was director of physical education at the University of Iowa for two years, and in 1903 became a member of the staff of the Massachusetts Memorial Hospitals.

Dr. Ruggles was professor emeritus of obstetrics at Boston University School of Medicine and had served as chief of the obstetric service at the Massachusetts Memorial Hospitals.

Among his affiliations were fellowships in the Massachusetts Medical Society and the American Medical Association, and memberships in the New England Obstetrical and Gynecological Society and the American College of Surgeons.

His widow and a daughter survive him.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MAY, 1940

| DISEASES | MAY 1940 | MAY 1939 | FIVE YEAR AVERAGE* |
|--------------------------|----------|----------|--------------------|
| Anterior poliomyelitis | 1 | 0 | 4 |
| Chicken pox | 1207 | 742 | 1091 |
| Diphtheria | 15 | 21 | 22 |
| Dog bite | 1422 | 1414 | 1259 |
| Dysentery bacillary | 15 | 5 | 6 |
| German measles | 109 | 91 | 2251 |
| Gonorrhea | 313 | 358 | 435 |
| Lobar pneumonia | 386 | 355 | 423 |
| Measles | 4060 | 4917 | 3415 |
| Meningococcus meningitis | 3 | 6 | 16 |
| Mumps | 943 | 679 | 993 |
| Paratyphoid B fever | 22 | 0 | 20 |
| Scarlet fever | 672 | 731 | 1027 |
| Syphilis | 518 | 462 | 470 |
| Tuberculosis pulmonary | 395 | 239 | 271 |
| Tuberculosis other forms | 31 | 30 | 29 |
| Typhoid fever | 17 | 2 | 6 |
| Undulant fever | 8 | 4 | 3 |
| Whooping cough | 756 | 635 | 634 |

*Based on figures for preceding five years.

RARE DISEASES

Anterior poliomyelitis was reported from Chicopee, 1, total, 1.

Diphtheria was reported from Boston, 2, Fall River, 3, Framingham, 1, Methuen, 2, North Andover, 1, Worcester, 6, total, 15.

Dysentery, bacillary, was reported from Attleboro, 3, Boston, 4, Deerfield, 1, Lowell, 6, Milton, 1, total, 15.

Infectious encephalitis was reported from Beverly, 1, Danvers, 1, total, 2.

Meningococcus meningitis was reported from Beverly, 1, Lynn, 1, Reading, 1, total, 3.

Paratyphoid B fever was reported from Arlington, 1, Bernardston, 1, Boston, 6, Concord, 1, Haverhill, 2, Lynn, 1, Medford, 2, Newton, 3, Pittsfield, 3, Quincy, 1, Worcester, 1, total, 22.

Pfeiffer bacillus meningitis was reported from Attleboro, 1, New Bedford, 2, total, 3.

Septic sore throat was reported from Amesbury, 1, Arlington, 1, Belmont, 1, Boston, 5, Fitchburg, 1, Foxboro, 1, Gardner, 1, Greenfield, 1, Leominster, 1, Lynn, 2,

Milford, 1 Quincy, 2 Weymouth, 1, Winchester 2 Wrentham, 1 total, 22.

Tetanus was reported from Saugus, 1 Wareham 1 total, 2.

Trachoma was reported from Everett, 1 Wakefield 1 total, 2.

Trichinosis was reported from Greenfield, 2 Hadley 1 North Andover 2 total 5

Typhoid fever was reported from Arlington 1 Middleboro, 1 New Bedford 1 North Attleboro 1 Norton, 4 Provincetown, 1 Somerville 6 South Hadley 1 Taunton 1 total 17

Undulant fever was reported from Adams, 1 Danvers 1 Middleboro, 1 Milton 1 Southbridge, 1 Swampscott, 1 West Boylston, 2 total 8.

Typhoid fever had its highest May incidence since 1931. A recent outbreak in the Metropolitan area is responsible for the greater part of this sudden increase.

The May incidence of undulant fever is higher than it has been since 1930. The reported cases are scattered throughout the State.

A recent outbreak of paratyphoid B fever in the Metropolitan area accounts for a sudden sharp rise in the reported incidence of this disease.

The reported incidence of dog bite is reaching its seasonal peak.

The incidences of chicken pox and measles are reported at levels slightly above the five-year average.

Anterior poliomyelitis and German measles are reported well below the five year average.

Gonorrhea, lobar pneumonia, meningococcus meningitis, mumps, bacillary dysentery scarlet fever and tuberculosis are reported at expected levels.

HARVARD MEDICAL SCHOOL

Selection of the three outstanding candidates for admission to the Harvard Medical School next fall as recipients of national scholarships offered by the school under Harvard University's "long-term" scholarship policy was recently announced. The winners are James S. Clarke, of La Grange, Illinois, A.B. Harvard 40 (Daniel Fiske Jones National Scholarship) Martin E. Flipse, of Douglaston Long Island, New York, A.B. Hope College 40 (Edward S. Harkness National Scholarship) and Winsor C. Schmidt, of Rye, New York, Sheffield Scientific School Yale (Harvard Medical School National Scholarship).

This is the fourth year of the medical school's national scholarship plan which is similar to that introduced by President James B. Conant in Harvard College in 1934 and subsequently adopted also by the Graduate School of Arts and Sciences, the Graduate School of Design and the Graduate School of Business Administration.

In addition medical-school scholarships totaling \$1300, for study during the next academic year were awarded as follows: Matthew and Mary E. Bartlett Scholarship to James P. Dixon, Jr., of Yellow Springs, Ohio S.B. Antioch 39; Abraham A. Watson Scholarship to Lytt I. Gardner of Reidsville, North Carolina A.M. University of North Carolina 40 and Isaac Sweetzer Scholarship to Frank E. Trobaugh Jr., of West Frankfort Illinois A.B. University of Illinois 40.

TUFTS COLLEGE MEDICAL SCHOOL

Ninety-seven students of the Tufts College Medical School received medical degrees at the college's eighty-fourth commencement exercises on Monday June 17.

The Annual Alumni Award a sphygmomanometer of special construction given to the graduate who is considered to have made the most progress in the four year course at the medical school was won by John D. Rice, of Worcester who received his premedical training at Bowdoin College. The Phi Delta Epsilon Gold Medal, for proficiency in the study of anatomy was given to Fred W. Thyng of Shapleigh Maine, who also received his premedical training at Bowdoin College. The name of the winner of the latter is inscribed each year on a bronze tablet in the medical school. Dr. Thyng received his degree cum laude. Others who received their degrees cum laude were Edward N. Cartmick, A.B. Harvard, of Clifton New Jersey Robert A. Hays A.B. Boston College, of Waltham Harvey W. Katz, B.S. Tufts College of Everett Leonard M. Klein A.B. Harvard of Roxbury Emil J. Koenig Jr., B.S. Massachusetts State College, of Jefferson Abraham Pollen B.S. Tufts College, Chelsea Stanley L. R. Robbins, B.S. Massachusetts Institute of Technology of Brookline Gertrude A. Rogers, A.B. Radcliffe, of Dorchester.

MIDDLESEX UNIVERSITY SCHOOL OF MEDICINE

The trustees of Middlesex University announce the appointment of Dr. Augustus Riley of Boston as dean of the medical school. Dr. Riley was born in Alabama in 1879 received his baccalaureate degree in arts from Oberlin College, and his medical degree from Harvard in 1907. After graduation he served an internship at the Long Island Hospital Boston, and a surgical internship at the Massachusetts General Hospital. He is a member of the American Urological Association and a fellow of the American College of Surgeons. He is assistant professor of genitourinary surgery at the Harvard Medical School where he has taught since 1911 and is visiting surgeon for urology at the Boston City Hospital. Dr. Riley will take office immediately.

MASSACHUSETTS SOCIETY FOR RESEARCH IN PSYCHIATRY

On May 2 1940 the Massachusetts Society for Research in Psychiatry was officially organized and held its first meeting.

The object of the society is to stimulate research in psychiatric medicine and its allied sciences in the psychiatric institutions of the Commonwealth. Members are made up of active and associate members, the active membership being limited to those who have completed or presented before a recognized scientific society or published in a recognized scientific journal results of research work which they have done within the last five years. This active membership will cease after more than three years have elapsed without production of original work, the member becoming an associate member. The associate members are selected from those having a background and training that renders them suitably qualified to become research workers, and from those who are participating in research work.

The meetings are to be held six times a year at the various hospitals in the Commonwealth engaged in neuropsychiatric work. They are to be devoted to symposiums and to informal discussions of projects, methods, techniques and demonstrations of research work actively engaged in or under discussion.

The following officers were elected for the coming year: president, Dr. William Malamud, vice-president, Dr. Paul Yakovlev, secretary-treasurer, Dr. Kenneth J. Tillotson.

CORRESPONDENCE

MILITARY PREPAREDNESS PROGRAM

To qualified physicians of Massachusetts the National Guard (26th Division) offers an opportunity to participate in the military preparedness program.

The 101st Medical Regiment and the medical detachments of the various combat units of the 26th Division are in the process of being expanded so that the advantage of early consideration of military service is obvious, both from the standpoint of choice of service and that of seniority.

All who are interested are urged to contact one of the officers of the Division Surgeon's Office, who will gladly discuss the various units and furnish information regarding qualifications, duties, pay and allowances. This office is located in the South Armory, Irvington Street, Boston, and is open Tuesday and Friday evenings from eight until ten o'clock.

Act now! The National Guard needs qualified physicians, and the latter need the practical experience which only service with troops can afford.

KARL R. BAILEY,
Colonel, M. C., Mass. N. G.,
Division Surgeon

REPORTS OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on March 5, with Dr. Max Ritvo presiding.

Dr. William B. Castle spoke on "Blood Dyscrasias: An aspect of general medicine." The importance of a complete history and accurate physical examination as well as blood studies in these conditions was stressed by Dr. Castle. The limitations of bone marrow biopsy in the diagnosis of anemias were contrasted with the greater definitiveness of lymph-node biopsy in differentiating the lymphoma group.

The blood dyscrasias were divided into groups depending on what can be expected from their treatment. Among preventable diseases Dr. Castle listed the hypochromic anemia of pregnancy and that associated with rapid growth in childhood, aplastic anemia and atypical leukemia due to industrial exposure to the cyclic compounds, and hemorrhagic disease of the newborn. Those in which cure or great benefit may be expected from proper therapy included congenital hemolytic jaundice, pernicious anemia without neurologic manifestations, "idiopathic" hypochromic anemia and hemorrhagic disease of the newborn. The third group consisted of conditions where treatment is of some help, such as polycythemia vera, chronic leukemia, idiopathic thrombopenic purpura, lymphoma, pernicious anemia with combined system disease, and malignancy complicated by treatable anemia.

The value of vitamin K in preventing as well as treating hemorrhagic disease of the newborn was emphasized. So-called idiopathic hypochromic anemia was attributed in most cases to apparent or occult blood loss and so should be attacked by discovering and stopping this loss and giving adequate iron therapy. Dr. Castle spoke of bleeding, with or without a low-iron diet, in order to pro-

duce the iron lack necessary to control the overactive blood production of polycythemia vera. The value of x-ray therapy in chronic lymphatic leukemia and the lymphomas was considered to lie in the increased duration of effective and comfortable life rather than in any prolongation thereof, except when local expanding lesions threaten vital structures. The neurologic manifestations of primary anemia can at least be arrested with adequate liver therapy. Finally, many patients with malignant disease can be made much more comfortable by caring for coincidental anemia.

Among the conditions which may be improperly diagnosed in the presence of blood dyscrasias, Dr. Castle cited heart disease, gastrointestinal disturbances, nephritis, neurologic lesions and liver disease. Unnecessary disability or dangerous procedures might result from false diagnosis. The speaker warned against splenectomy unless congenital hemolytic jaundice or idiopathic thrombopenic purpura has been surely diagnosed, against roentgen therapy in the possible presence of aplastic anemia or non-leukemic myelosis and against ill-advised surgery in untreated scurvy, hemophilia or vitamin K deficiency. A mistaken diagnosis may lead to an erroneous prognosis. Thus a patient given a hopeless prognosis from supposed leukemia may live indefinitely to taunt the doctor after recovery from his infectious mononucleosis. The converse may also occur. Proof of poor diagnosis was illustrated by statistics on pernicious anemia, where in a series of 100 patients the average delay from the onset of definite symptoms to the making of the correct diagnosis was almost a year and a half. In those whose original symptoms were alimentary, the diagnosis was not made on the average for almost three years.

The anemias were divided into two large groups, those in which the demand for red cells exceeds the supply and where the bone marrow is physiologically active, and those in which the supply is deficient for even a normal demand and the marrow activity is depressed. The first group includes the two large subgroups of acute blood loss and increased blood destruction. The latter subdivision is made up of extrinsic causes such as chemicals and infections, and intrinsic ones such as abnormal erythrocytes or abnormal plasma. The large division exhibiting poor hematopoiesis includes nutritional, hormonal, toxic (benzene), physical (x-ray), mechanical (malignancy) and idiopathic causes. In those anemias caused by encroachment of malignant tissue on the marrow there is a false activity mirrored in the peripheral blood as a result of overworking of the reduced amount of effective hematopoietic tissue.

Dr. Castle went on to discuss criteria for the diagnosis of certain of the blood dyscrasias, emphasizing the importance of at least a hemoglobin determination and a blood film in every patient. These will prevent gross oversight and will serve to indicate the need for more extensive blood studies. Hypochromic anemia can be diagnosed by blood examination alone, for the only possible similarity appears in chronic infection. Congenital hemolytic jaundice is characterized by a significant increase of the erythrocyte fragility due to the predominance of spherocytes. In most instances, however, the diagnosis cannot be made without, in addition, a careful history and physical examination. In pernicious anemia, these were considered particularly important, for the symptoms may follow the characteristic symptom pattern of stomatitis and neural manifestations. It was pointed out that such symptoms may occur with only minimal anemia.

Dr. Castle briefly discussed the two theories as to the pathogenesis of pernicious anemia. One holds that the liver extract necessary for erythrocyte maturation is formed

by the action of the gastric secretions on some food substance, probably a portion of the vitamin B complex. Rhoads, on the other hand, believes there is a toxin which causes hemolysis only in the presence of malnutrition. In describing the current method of treating pernicious anemia, Dr Castle emphasized that the U.S.P. unit of liver extract used is based on a satisfactory hematopoietic response and does not necessarily indicate the therapeutic effectiveness on gastrointestinal or central nervous system manifestations of the disease. The speaker advocated the use of 5 to 10 U.S.P. units intramuscularly on each of the first two or three days, and a minimal maintenance dose of 15 units intramuscularly each week for about three months, at which time it may be halved if the clinical and hematological condition is satisfactory. The oral administration of liver extract was considered undesirable, especially in patients with severe anemia or combined system disease, because of the possible failure of a certain proportion of patients to respond.

Dr Castle then considered the hypochromic anemia of iron deficiency which is found especially during the period of rapid growth at puberty in pregnancy and in bleeding of all sorts. The considerable loss of iron during the menstrual cycle of women was stressed as an important cause of so-called "idiopathic" hypochromic anemia. Studies of the effect of maternal anemia on the infant showed that there is no relation to the infant's level at birth, but that children of anemic mothers are prone to the development of anemia at about one year. The indiscriminate use of expensive liver extract in undiagnosed anemias was deprecated because of the possibility of confusion as to what brought about recovery and also because it might commit the patient to an unnecessary life of continuous liver therapy.

There was a brief consideration of the significance of certain findings on blood examination. Leukopenia might be found in influenza, measles, typhoid fever, undulant fever, malaria, catarrhal jaundice, the Felty syndrome, agranulocytosis, aleukemic leukemia, Banti's syndrome, aplastic anemia, pernicious anemia and cirrhosis of the liver. It was emphasized that in agranulocytosis there is usually little evidence of depression of the red blood cells and platelets, which are, however, affected in aplastic anemia and aleukemic leukemia.

Among common conditions causing lymphocytosis were cited pertussis, measles, rickets, tuberculosis, infectious mononucleosis and the lymphatic leukemias. The latter two diseases were particularly stressed, and the diagnostic value of the heterophile agglutination test in mononucleosis was emphasized. The complexities of the clinical manifestations and terminology of the leukemias and lymphomas were explained by an analogy to the different manifestations of staphylococcal infections: furuncle, osteomyelitis, septicemia.

Dr Castle concluded with a brief résumé of hemorrhagic disease. This was divided into vascular platelet and coagulation defects. Conditions of the first group were infections, arteriosclerosis, congenital thrombasthenia, nutritional deficiencies (vitamin C) and allergic diseases, such as Henoch's purpura. Thrombopenic purpura was subdivided into symptomatic, which may occur in aplastic or myelophthisic anemia or leukemia, and "essential" which includes allergy to drugs and the idiopathic form. In the latter there is usually no decrease of leukocytes and erythrocytes, the bleeding time is prolonged, the clotting time normal and the tourniquet test positive, whereas the platelets are reduced. Splenectomy is the only but not a regularly effective treatment for idiopathic thrombopenic purpura.

The discussion was opened by Dr M. B. Strauss, who stated that more than 12 patients have been seen at the Boston City Hospital in the past two years who were unnecessarily under liver therapy for a mistaken diagnosis of pernicious anemia. It was claimed that repeated doses of liver extract intramuscularly at intervals of not more than four weeks are preferable to single large doses at less frequent intervals.

Dr Henry Jackson Jr. reiterated the importance of studying the patient as a whole rather than merely the blood. He stated that a definite sequence of events occurs in bone marrow failure and may account for the variable peripheral blood picture during the course of a disease. Anemia can take place only with time, thus it is gradual in such conditions as leukemia. Dr Jackson cited the importance of distinguishing myeloid metaplasia from chronic myelogenous leukemia and hemolytic jaundice, either of which it may simulate. X-ray therapy in the first instance or splenectomy in the second would undoubtedly prove fatal if the wrong diagnosis were made.

Dr B. M. Jacobson advocated the routine use of Hayem's rather than Gower's solution for red-blood-cell counts for in this way one may note a precipitation of the mercury bichloride in the presence of an elevated serum globulin, such as is found in liver disease and multiple myeloma. He reminded the audience that although nutritional anemias are decreasing, the advent of new drugs has offset this improvement by producing other kinds of anemia.

Dr Wyman Richardson discussed "splenic anemia" a term loosely used in anemias associated with splenomegaly. Splenomegaly is known to have some relation to leukopenia but Dr Richardson doubts that the same can be said for anemia. He believes that there is always hemorrhage to account for hypochromic anemia and that thrombosis of the splenic vein may cause this. Splenectomy was not advocated.

Dr William Dameshek emphasized the importance of interpreting blood findings on a physiological basis. He mentioned the rare cases of hemolytic anemia with jaundice but no bilirubinuria which may be benefited by splenectomy. Dr Dameshek stated that splenectomy does affect the bone marrow in purpura, for there seem to be abundant megakaryocytes but no platelet formation.

BOSTON ORTHOPEDIC CLUB

A regular meeting of the Boston Orthopedic Club was held at the Boston Medical Library on March 11 with Dr Armin Klein presiding.

The speaker of the evening was Dr Warfield M. Frior who spoke on "Recent Experimental and Clinical Observations on Tetanus." The first part of the discussion was devoted to recent experiments performed at the Johns Hopkins University School of Medicine in an attempt to disprove the neural transmission of tetanus toxin and to determine the true mechanism of the pathogenesis of the resultant disease.

The original work was initiated by Abel who by careful technique showed that local tetanus does not result from sciatic injection of the toxin and that antitoxin injected into the nerve proximal to the toxin does not prevent local tetanus unless it is allowed to leak out into the surrounding tissues. It is believed that the fallacy of Meyer's experiments, which seemed to indicate that tetanus toxin is transmitted by peripheral nerves, consisted in allowing leakage from the nerve. Abel was also able to perfect a method for producing local tetanus which lasted for three months before the muscle returned to normal. Multiple intramuscular injections totaling only one two-hundredths

of a lethal dose of the toxin resulted in an unyielding rigidity that was considered a true peripheral manifestation of the disease, the site of action being the neuromuscular end-organs

In order to prove that both rigidity and convulsive spasms result from the action of tetanus toxin on the anterior horn cells of the cord, Meyer injected toxin directly into the spinal cord. He obtained an extremely painful form of the disease which he called tetanus dolorosus. In repeating these experiments Dr. Firor was able to avoid this painful complication by rotating the cord before injecting the toxin into the anterior horns. These injections produced tactile reflex tetanus without inducing any muscular rigidity. With tactile reflex tetanus the slightest sensory stimulus initiates a series of clonic spasms that last for two or three minutes.

Although this seemed to be a central form of the disease without true peripheral manifestations, the puzzling fact was that the animals all died, even when only a small fraction of an ordinary lethal dose was employed. Various hypotheses were suggested to account for this lethal phenomenon. That a metabolic poison from the convulsions was not responsible was proved by separating the cauda equina from the spinal cord and then injecting the stump so that peripheral contractions did not occur, and yet death occurred. To disprove the ascent of the toxin in the cord a sizable section of the cord was resected and the toxin put in the distal portion, but still the animals died. That the course is not affected by the site of injection was shown by the presence of a similar incubation period of well being, even when the toxin was introduced into the medulla. That multiplication within the cord does not explain the peculiar lethal effect was proved by transplantation of the injected segment. Finally antitoxin was administered intravenously prior to intraspinal injection of the toxin to rule out multiplication in the blood stream, but such animals succumbed with an excess of antitoxin in the circulating blood.

Control experiments consisted of the similar injection of other toxins, none of which caused death except diphtheria toxin, and this was due to extensive necrosis of the cord, the injection of tetanus toxin into other organs without the potentiation found in the central nervous system, and the injection of tetanus toxin into the spinal cord of other species that showed the same phenomenon to varying degrees, depending upon their sensitivity. It was found that cats require nine hundred times as much toxin injected intravenously as do guinea pigs, but when given intraspinaly one guinea pig lethal dose per kilogram causes death in all the species tested, therefore, it was concluded that resistance is proportional to the presence of some mechanism preventing the toxin from reaching the sensitive nervous tissue. These observations led to the hypothesis that tetanus toxin is fixed on reaching the central nervous system, where it is either altered or liberates a new substance which is responsible for the lethal effect and is not amenable to antitoxin.

By using cross-circulated dogs it was determined that a recipient presaturated with antitoxin lived, while the donor treated with toxin died if the mixing of the blood was done before symptoms began in the donor. But if the crossing was carried out subsequent to the onset of symptoms, the recipient and the donor died at about the same time and with similar symptoms despite the use of antitoxin beforehand in the recipient, consequently, this seemed further evidence that something other than tetanus toxin was effective in the recipient. That the quantity of toxin administered is important was demonstrated by experiments which showed that a third of a lethal dose given

intravenously caused no symptoms, but a half to three quarters resulted in characteristic symptoms.

An interesting practical observation was that barbiturates and other commonly employed respiratory depressants appeared to affect toxic animals more deleteriously than normal ones. It was considered that this was a synergistic action between these drugs and the tetanus toxin that kills essentially by respiratory inhibition. The suggestion was advanced, therefore, that such medication is not rational for the control of the convulsions of tetanus.

In regard to the efficacy of antitoxin, it was stated that this can save life if administered before injury or before symptoms develop if the dose is huge, but never after symptoms have become established. It seems that after one lethal dose of tetanus toxin is fixed, incubated and altered in the central nervous system, no amount of antitoxin can be lifesaving. The amount of antitoxin necessary in any case was held to depend on the route of entry of the toxin, for it was found that the intramuscular site of toxin injection requires ten times and the intraspinal ten thousand times the dose of intravenous antitoxin. Dr. Firor stated that preliminary animal experiments indicate that intrathecal administration of antitoxin may be more beneficial than is the intravenous route.

As a result of these experiments the theory has been postulated that the tetanus organism develops only in the presence of already existing infection, and that the toxin then diffuses through the tissue fluids to reach the local neuromuscular end-organs and produce local tetanus, thence it reaches the blood stream and a small amount is fixed on reaching the central nervous system, but this produces no symptoms. There the toxin either is altered or alters the tissue, and tactile reflex tetanus then appears. A certain amount of this changed material reaches the systemic circulation and death results from respiratory failure. The outcome, therefore, is determined by the amount of tetanus toxin reaching the central nervous system, where it is fixed and altered.

Dr. Firor then discussed the treatment of human tetanus in the light of this work. The site of injury is determined, if possible, and infiltrated with antitoxin an hour before doing a thorough débridement. This precautionary delay was considered advisable in order to prevent local tetanus from squeezing out the toxin during manipulation. Fifty thousand units of antitoxin are administered intravenously, for this has been found an adequate dose against any conceivable infection. The fluid balance is carefully maintained, and the choice of sedatives is paraldehyde, chloral, or ether in oil by rectum.

Prophylaxis is now concerned with active as well as passive immunization, it was pointed out. Passive immunization can be conferred by 1500 units of antitoxin, which will result in a titer of 0.1 unit of antitoxin per cubic centimeter of blood for the succeeding four or five days. Active immunity as produced with toxoid has proved beneficial in army horses, and has been advocated for routine use in farmers and workers in hazardous industries as well as in soldiers. One cubic centimeter of the toxoid injected subcutaneously produces no discernible antibody response, but when followed in eight to twelve weeks with at least one more such injection there ensues a solid protection for two months to a year. Even after the immunity has worn off, subsequent administration of the toxoid results in a rapid rise of the titer, and Dr. Firor advocated such injections every three months for those constantly exposed to tetanus infection. The blood level was found to reach 5 to 15 units of antitoxin per cubic centimeter. No reactions were encountered except for

slight local soreness and there were no failures with the three injection method.

The discussion was opened by Dr LeRoy Fothergill, who explained the difference in reactions following toxoid vaccinations against tetanus and diphtheria. He stated that the latter is really due to sensitivity to the bacillary protein following repeated subclinical exposures to the diphtheria bacillus, a factor which is lacking in respect to tetanus. Although the lack of a sensitivity test comparable to the Schick test was noted, Dr Fothergill stated that this was not a serious drawback, for a properly carried out inoculation results in practically 100 per cent "takes."

Dr Fothergill could find no a priori basis for expecting that the intrathecal use of antitoxin should be better than the intravenous. He asserted that it is more difficult to reach the anterior horn cells through the vascular meninges than via the blood stream furthermore there is a local irritation of the already sensitive spinal cord. It was hypothesized however that such an irritation might increase the permeability of the blood-brain barrier and thus prove effective. Dr Firor agreed with this theory.

NOTICES

ANNOUNCEMENT

EDWARD H. HODDIE, M.D., announces the removal of his office from 515 East Broadway South Boston to 186 Dorchester Street, South Boston.

FELLOWSHIPS IN CHILD PSYCHIATRY

A limited number of fellowships have been provided by the Commonwealth Fund and by other sources for training in extramural especially child psychiatry. These fellowships are to be administered by the National Committee for Mental Hygiene through which fellows are to be assigned for one or two years to a selected child-guidance clinic, the term and plan of the fellowship to be determined by the peculiar needs of the fellows. Candidates should have had at least two years of psychiatry in an approved mental hospital in addition to other qualifications fitting them for extramural service. These fellowships come in response to a definite paucity of personnel in this field. Accordingly conditions as to age, sex, marital status and so forth must be governed by individual cases and by the nature of current demand. Requests for further information about these fellowships, and application therefor should be addressed to Dr. Milton E. Kirkpatrick, National Committee for Mental Hygiene, Room 822, 50 West 50th Street, New York City.

BOOKS RECEIVED FOR REVIEW

The Conservation of Intelligence Theodore R. Robie. 75 pp. Montclair New Jersey privately published, 1940.
Sex in Marriage Ernest R. Groves and Gladys H. Groves. 750 pp. New York Emerson Books Inc., 1940. \$2.00.

Psychological and Neurological Definitions and the Unconscious Samuel Kahn. 219 pp. Boston Mador Publishing Co. 1940 \$2.00.

The March of Medicine Edited by the Committee on Lectures to the Lany of the New York Academy of Medicine. 168 pp. New York Columbia University Press, 1940 \$2.00.

Social and Biological Aspects of Mental Disease Benjamin Malzberg. 360 pp. Unica New York State Hospitals Press, 1940. \$2.50.

Principles of Surgical Care Shock and other problems Alfred Blalock. 325 pp. St. Louis C. V. Mosby Co. 1940 \$4.50.

A Manual of Neurohistologic Technique Oscar A. Turner. 73 pp. St. Louis C. V. Mosby Co., 1940. \$2.00.

Principles of Hematology Russell L. Haden. Second edition 362 pp. Philadelphia Lea & Febiger 1940. \$4.50.

Studies from the Rockefeller Institute for Medical Research Vol. 115 622 pp. New York The Rockefeller Institute for Medical Research 1940. \$2.00.

The Era Key to the USP XI & NF VI Revised by Lyman D. Fonda. Fifth edition. 320 pp. Newark Haynes & George Co., Inc. 1939 \$1.00.

The Diagnosis and Treatment of Pulmonary Tuberculosis John B. Hawes, 2d and Moses J. Stone. Second edition 260 pp. Philadelphia Lea & Febiger 1940. \$2.75.

An Introduction to Biochemistry William R. Fearon. Second edition. 475 pp. St. Louis C. V. Mosby Co. 1940 \$3.75.

BOOK REVIEWS

Ptoses gastriques et coliques doctrine—clinique thérapeutiques M. Chiray and P. Chêne. 270 pp. Paris: Masson et Cie 1939 75 Fr fr.

The authors begin by deploring the frequency and carelessness with which the diagnoses of ptosis of the stomach and colon are made, since this diagnosis predicates a long and rather rigorous therapeutic regime. Nevertheless their own criteria for making the diagnosis may be open to criticism. The monograph on the whole is a rather verbose discussion of the various aspects of this subject which although taken up systematically offers very little that is new or enlightening. Some of the case histories presented make the treatise easy to read. The volume should be of interest to gastroenterologists as indicating the point of view which their authoritative French confreres have on this subject.

Diagnosis and Management of Diseases of the Biliary Tract R. Franklin Carter Carl H. Creene and John R. Twiss. 432 pp. Philadelphia Lea & Febiger 1939 \$6.50.

The authors present a large mass of data in support of their hypothesis that the gall bladder and biliary tract are the sources of many gastrointestinal symptoms of vague nature even though the gall bladder is not grossly or obviously diseased. They describe the gall bladder and the biliary tract in various states of "biliary dyskinesia" as producing many of the common symptoms of functional

digestive disease and advocate the treatment of such symptoms by bland low residue diets, either rich or low in fats, by antispasmodics and sedatives, by attention to bowel habits and by repeated therapeutic duodenal drainage.

There can be no argument with that part of the authors' work dealing with physiology and the application of diagnostic methods. The section on surgery covers well the present day thought on surgical practice in diseases of the gall bladder and biliary tract.

On the other hand, there can be and is a vigorous school opposed to the principal thesis of the book, namely the treatment of so-called non-calculous cholecystitis or 'biliary dyskinesia'. Many of the conditions which they ascribe to the biliary tract could, with equal justice, be ascribed to other parts of the digestive apparatus and could be treated with equal effectiveness by ignoring the liver and its appendages and concentrating on the presenting symptoms and the more obvious functional disturbances of the gastrointestinal tract as a whole.

The authors believe in prescribing low cholesterol diets, and report a lowering of the blood-cholesterol level and symptomatic improvement on such diets. As attractive as this theory may be, the reviewer is of the opinion that there is no good reason to believe that the lowering of the blood-cholesterol level should improve gall bladder function. Low cholesterol diets are in the main low fat diets, the latter having been used for years in the management of chronic gall bladder disease. If cholesterol can be absorbed from the gall bladder wall or from precipitated cholesterol in the gall bladder, a more likely approach would appear to consist of stimulation of bile flow by chologogues or high fat diets.

A Symposium on the Blood and Blood Forming Organs
By fifteen authors. 264 pp. Madison, Wisconsin University of Wisconsin Press, 1939. \$3.50

This volume deals with most of the material presented at the Institute for the Consideration of the Blood and Blood Forming Organs, held at the University of Wisconsin Medical School on September 4, 5 and 6, 1939. The institute, which lasted three days, was a brilliant success, both in the size, type and enthusiasm of the audience and in the quality of the subjects presented. Minutes of hematological morphology, so commonly discussed at similar European conferences, were for the most part set aside for considerations of the physiological concepts of disease.

The volume is highly recommended to the many physicians who have more than a passing interest in hematology. A charming discussion by Meulengracht on the history of hematology is followed by an erudite and important article on the porphyrins by Watson. Watson's style is a bit formidable but the article is worth digging through. Rhoads presents his comprehensive studies on what he chooses to call 'aplastic anemia' or 'refractory anemia'. Many diverse conditions are indiscriminately grouped in this category, but one must credit the writer with the brilliance of his concepts and his ability to find 'least common denominators' for apparently diverse conditions. Heath gives a synopsis of his work on anemia due to iron deficiency. Minot presents an abstract of his ideas on the anemias of nutritional deficiency, and Diamond gives a didactic discussion of the erythroblastic anemias. Then follow brilliant papers by Meulengracht on "Some Etiological Factors in Pernicious Anemia" and by Haden on "The Nature of Hemolytic Anemia". The latter is a comprehensive article discussing thoroughly the question of the spherocyte and the fragility test. Furth gives an excellent presentation of experimental leukemia

with its human correlations, and Forkner has a well documented article on monocytic leukemia. In his article on Hodgkin's disease, Krumbhaar presents some new work utilizing tissue-culture technique, if confirmed, this preliminary investigation would seem to indicate an infectious rather than a malignant basis for the condition. Doan has a very stimulating article on the reticuloendothelial system, in which are discussed such apparently unrelated subjects as hemolytic anemia, thrombocytopenic purpura, "primary splenic granulocytopenia" and monocytic leukemia, the spleen is said to be the center for these diverse conditions. Downey has a good morphological discussion of infectious mononucleosis, and the subjects of polycythemia and of marrow cultures are discussed by Reznikoff and Osgood respectively. Eagle's presentation of the "Blood Coagulation Problem" is excellently done and contains an extensive bibliography.

All in all, the volume is well worth owning, giving as it does much of the present-day work in the numerous fields of hematology. This first American Institute of Hematology indicates the greatly increased interest in the subject in this country and may well be the prelude to other equally successful gatherings in this field.

Bacteriology Clin Medica 22 William W Ford. 207 pp. New York and London Paul B Hoeber, Inc., 1939. \$2.50

This small book, which comes to join the excellent *Clin Medica* series on medical history, sets forth in a succinct but capable and interesting manner the significant theories and discoveries whereon modern bacteriology rests. In accord with the purpose of this series, which is to make available primers or straightforward statements of the important historical facts in each subject, the author of the present volume confines himself largely to outlining those fruitful investigations which have given impetus from time to time to broad advances in knowledge.

Thus we find recounted the development of optical science, which like so many others expanded rapidly in the congenial atmosphere of the late Renaissance. Here the contributions of Anton van Leeuwenhoek to the perfecting of simple lenses and Galileo's invention of the compound microscope are emphasized. Although such improvements in magnification as early as 1683 enabled Leeuwenhoek to see and describe bacteria so clearly that no doubt can exist concerning the accuracy of his observations, scientists of the eighteenth century surprisingly failed to take advantage of this momentous discovery. Their most notable offering, perhaps, is to be found in the experimentation of Spallanzani, which should have ended the impeding controversy over spontaneous generation. Jenner's magnificent experiments, not reported until the very end of the century, and never to be too often called to mind, are possibly given inadequate treatment in view not only of their great practical value but because of the immunological principles which they illuminate so brilliantly.

The remainder of the book is largely occupied with the work of the great masters, Pasteur and Robert Koch, and with the immediate harvest of new knowledge to which this gave rise. The story is, of course, familiar to all bacteriologists, but Professor Ford has told it well, and it is of value to have here readily available. A final chapter on later developments reviews most of the important conceptions in both bacteriology and immunology established by the researches of the first quarter of the present century.

Not the least pleasing feature of the book is the rather extensive and well arranged bibliography.

Housing Yearbook 1939 Edited by Coleman Woodbury
240 pp. Chicago National Association of Housing
Officials, 1939 \$3.00

Poor housing, disease and poverty are an anti-social tri-umvirate that have always moved together. As physicians have become more socially aware of the interrelatedness of social phenomena they have also become more concerned with doing what they can, both as citizens and as physicians, to break up this alliance.

This useful volume describes the federal state and local activities in housing and reviews the work of the Federal Housing Administration and of the Home Owners Loan Board, and the housing activities of the Farm Security Administration. It concludes with a directory of housing agencies.

There are four very illuminating chapters written by Nathan Straus, Stewart McDonald, J. H. Fahey and W. W. Alexander.

It is impossible, in a brief review to give the reader any conception of the range of useful facts to be found in this little volume. Here are a few selected at random, on the Home Owners Loan Corporation (HOLC). In the low of the depression there were a thousand foreclosures a day. The HOLC took over mortgages totaling \$932,000,000 from banks and trust companies, \$767,000,000 from savings and loan associations, \$192,000,000 from financing and mortgage companies and \$164,000,000 from insurance companies. Thus the HOLC assisted these institutions in remaining liquid. This permitted the institutions to grant leniency to other distressed home owners and to lend to needy borrowers. The HOLC paid \$229,000,000 to wipe out delinquent taxes and saved home owners \$175,000,000 in interest by virtue of the Government's greater borrowing power. Of course, the HOLC has had to foreclose on some properties. But in nearly 90 per cent of such cases the "owners" were more than a year in arrears on principal and interest payments in 63 per cent, the period was more than a year and a half. Twenty per cent of the foreclosures were voluntary, an estimated 18 per cent of the foreclosed properties being either abandoned or virtually so. J. H. Fahey, chairman of the board recommends that the HOLC, rather than expending its revenues on hopeless cases, should now aid only those who have a real possibility in saving their homes, "so that the corporation may wind up its operations without great loss to taxpayers."

The other articles are similarly crammed with fascinating facts on housing which are of substantial value to all students of these problems. The articles make clear to doubters that our housing problem is in the hands of able, conscientious administrators—all of which should give us confidence for the future.

Fractures Paul B. Magnuson Third edition. 511 pp.
Philadelphia: Montclair and London: J. B. Lippincott
Co. 1939 \$5.00

The author explains that the purpose in writing this text was "to meet the needs of the man who first sees the fracture" which limits the scope of the book to a more or less elementary discussion. Such a viewpoint has its advantages and disadvantages, both of which become apparent. The groundwork is well presented. Anatomical descriptions are worked out to explain the mechanical distortion which follows loss of skeletal support at various locations. The discussions of treatment are clear outlining varieties of methods in general use. There is a wealth of clinical suggestion, warning the practitioner of complications which may be anticipated and suggesting meth-

ods to escape them. Descriptions of operative technique avoid minute details and are limited to the basic principles.

On the other hand, fracture treatment is advancing so rapidly that even a general text should include an ampler discussion of progressive methods than is here afforded. Intra-articular fractures of the neck of the femur for example, are discussed so indecisively that one turns back to the title page to see if it is actually 1939 and not 1929. More space is given to the Whitman spica method than to Smith-Petersen's or Moore's nailing. We search in vain for reference to walking irons on casts or to skeletal traction for fracture-dislocations of the cervical vertebrae. Not a word of mention is given to the principles of double-pin fixation advocated by Anderson. Neither drilling nor nailing of slipped, upper femoral epiphyses is suggested as a possibility, the old-fashioned clavicular cross being the only method mentioned for this common fracture. Such omissions detract from the value of a text of this sort.

Manual of Urology R. M. LeComte. Second edition.
295 pp. Baltimore: The Williams & Wilkins Co.,
1939 \$4.00

In this book the author has succeeded in presenting a remarkably concise and well-balanced treatise on diseases and disorders of the genitourinary organs. No condition of importance has been omitted and the opinions expressed by him are representative of those which are commonly held by urologists. Although these opinions are stated emphatically and somewhat didactically the author has departed from this attitude when commenting on subjects which are not yet clearly understood.

The reviewer noted only two statements with which he would not agree. On page 262, in the paragraph on treatment of testicular tumors, the author writes "In cases with inoperable metastases, deep x-ray therapy may afford striking relief over long periods of time." The reviewer believes that the value of deep x-ray therapy as a preventive of the development of such metastases has been fully established. On page 263 it is stated that simple puncture of a hydrocele "is fraught with the dangers of hemorrhage and infection." In the reviewer's experience these complications occur but rarely.

Aside from these two criticisms, the reviewer has nothing but praise for this manual and believes it will prove a valuable reference book for those who wish to acquire a general idea of genitourinary diseases.

Maternal Care and Some Complications The principles of antepartum, intrapartum and postpartum care and of the management of some serious complications
Edited by F. L. Adair 194 pp. Chicago: University
of Chicago Press, 1939 \$1.50.

The first section of this little book is on maternal care and it is a very clear concise exposition of the care that any woman who is pregnant should receive from her physician. The second section takes up a few of the more common complications of pregnancy: the toxemias, obstetric hemorrhages and puerperal infection.

If this book were placed in the hands of every practitioner of medicine who is doing obstetrics and if he would honestly and conscientiously follow out the suggestions and technique so carefully outlined, there is no question that a great improvement in obstetrics as practiced in this country would follow.

Psychobiology and Psychiatry: A textbook of normal and abnormal human behavior Wendell Muncie. 739 pp. St. Louis C V Mosby Co., 1939 \$8 00

This book, containing a foreword by Adolf Meyer, represents, as is stated in the preface, an attempt to put before students the concepts, teaching and working methods of the Henry Phipps Psychiatric Clinic of the Johns Hopkins Hospital. The important role which this clinic has played in psychiatric thought in America and abroad is too well known for comment. A textbook that presents the teaching methods of the clinic will be viewed with interest by all psychiatrists.

The book is composed of four parts. Part one deals with the study of normal behavior—the 'material' of Adolf Meyer's ergasiology. After a brief historical account, and a presentation of what the author recognizes as the philosophical bases of psychobiology, ninety-three pages are devoted to an elaboration of Meyer's familiar students' personality study. Part two deals with abnormal behavior—the reaction types, or pathergasias, of the Meyerian school of psychiatry. Part three, consisting of seventy-seven pages, is allotted to treatment. Part four is a tabulated survey of the development of the concepts underlying clinical states which the author designates as reaction sets. This section is poorly arranged. Many of its one hundred and eighty-six pages are unnecessarily blank. For example, the part concerned with parergasia (schizophrenia) might well have included references to Clouston's "dementia of adolescence" and to Carl Wernicke's "sejunction"—a forerunner of Bleuler's schizophrenia concept.

It is the reviewer's opinion that the book is not a complete textbook of psychiatry to be compared with that of Henderson and Gillespie. It is a book which, as has been stated, presents the conceptions, teaching and working methods of the Henry Phipps Psychiatric Clinic—as they have developed under the guidance of Adolf Meyer.

Physiotherapy in Medical Practice Hugh Morris. 276 pp. Baltimore The Williams & Wilkins Co., 1939 \$4.50

"This book is not intended for the specialist but for the practitioner who wants to know what he can expect from electrotherapy and who prefers to prescribe the treatment to be given to his patients instead of leaving the choice to a masseuse, as is so often done." This quotation from the preface not only designates the group of physicians for whom the book was written but also implies a just criticism of the others who stoop to the technician not only for the technical application of physical therapy but even for the medical judgment to be exercised in choosing a given physical agency or modality.

In relatively few pages the author has managed to do justice to the physics, physiological effects, indications and technic of application of the various measures commonly employed by the average physical therapist. This was made possible by the author's knowledge of the underlying principles of the subject matter which he covers and by his economical style of writing.

Certain minor improvements can be suggested. His explanation of induction is altogether too brief and somewhat involved, considering that it represents the most important method of generating electricity, the latter being the backbone of the entire treatise. To the faradic coil, which forms an important part in the testing of paralysis, he has allocated only five lines, while a page is devoted to the dynamo-and motor current. In discussing the static

machine he speaks of the principle of induction but makes no reference to that of friction, notwithstanding the fact that the latter gives the initial charge. Again, poor judgment has been used in the allocation of pages. The static machine is used very little as compared with short wave apparatus, yet the consideration of the former takes up ten pages whereas that of the latter is given only seven. However, these shortcomings are of minor importance compared with the advantages that this book has over other texts of similar nature. It is brief, yet covers its ground well and fulfills the aim of its author, namely, to supply the general practitioner with the necessary knowledge of principles, skill of application and sound judgment to be exercised when prescribing and applying the various measures of physical therapy.

Modern Clinical Psychiatry Arthur P. Noyes. Second edition. 570 pp. Philadelphia and London W B Saunders Co., 1939 \$5 00

No book deserves the word "modern" in its title more than this, because it rejects *en masse* the accumulated learning of a generation or two of scientists and presents its current point of view exclusively even though tempered. The long line of doctors who insisted that persons with mental disease were sick and should have medical care at once disposed of forthwith. For instance on page 89 it is stated "The minor and many of the major psychoses should not be considered as 'diseases' in the usual sense of the term but as an individual's unwholesome, poorly adjusted methods of reaction to his particular stresses and problems."

What we call mental disease is therefore not a disease entity but an individual problem in human behavior, a problem in personality maladjustment." All will, of course, agree with the statement (page 95) "Mind is an integral function of the organism and can not be split up into components", but shall we also accept the taboo, "We must therefore not think of it as a sort of machine different parts of which sense, perceive, imagine, remember, associate, reason about, desire, choose etc."? Krepelin is not included in the bibliography at the end of the chapter, "Symptoms of Mental Disease", in fact, the old gods are fairly well dethroned. The new ones are accepted with the zeal of a missionary. There is even a paragraph on psychogenesis in the description of paresis.

This is a good book, well written and showing much erudition. It perhaps expresses the high tide of the psychological approach to mental disease, certainly advancing medical knowledge in no other way.

An Introduction to Genetics A H Sturtevant and G W Beadle. 391 pp. Philadelphia and London W B Saunders Co., 1939 \$3 25

The authors treat the subject of genetics as a mathematically formulated subject that is logically complete and self-contained. Readers should be familiar with elementary biology and have an understanding of the simple laws of probability to appreciate the handling and interpretation of the genetic data contained in this book. The reviewer believes that the material is presented in a noteworthy, concise manner wholly consistent with the effort to teach students the fact that genetics is largely a science of ratios. At the end of each chapter the authors give problems well calculated to arouse interest and enthusiasm on the part of students. There are many good diagrams and figures.
